The new title compound, disodium dizinc iron(III) tris(phosphate), $\mathrm{Na}_{1.67} \mathrm{Zn}_{1.67} \mathrm{Fe}_{1.33}\left(\mathrm{PO}_{4}\right)_{3}$, which belongs to the alluaudite family, has been synthesized by solid-state reactions. In this structure, all atoms are in general positions except for four, which are located on special positions of the $C 2 / c$ space group. This structure is characterized by cation substitutional disorder at two sites, one situated on the special position $4 e(2)$ and the other on the general position $8 f$. The $4 e$ site is partially occupied by $\mathrm{Na}^{+}[0.332$ (3)], whereas the $8 f$ site is entirely filled by a mixture of Fe and Zn . The full-occupancy sodium and zinc atoms are located at the Wyckoff positions on the inversion center $4 a(\overline{1})$ and on the twofold rotation axis $4 e$, respectively. Refinement of the occupancy ratios, bond-valence analysis and the electrical neutrality requirement of the structure lead to the given composition for the title compound. The threedimensional framework of this structure consists of kinked chains of edgesharing octahedra stacked parallel to [101]. The chains are formed by a succession of trimers based on $\left[\mathrm{ZnO}_{6}\right]$ octahedra and the mixed-cation $\mathrm{Fe}^{\mathrm{III}} / \mathrm{Zn}^{\mathrm{II}}$ $\left[(\mathrm{Fe} / \mathrm{Zn}) \mathrm{O}_{6}\right.$ ] octahedra $\left[\mathrm{Fe}^{\text {III }}: \mathrm{Zn}^{\text {III }}\right.$ ratio 0.668 (3)/0.332 (3)]. Continuous chains are held together by $\mathrm{PO}_{4}$ phosphate groups, forming polyhedral sheets perpendicular to [010]. The stacked sheets delimit two types of tunnels parallel to the $c$ axis in which the sodium cations are located. Each $\mathrm{Na}^{+}$cation is coordinated by eight O atoms. The disorder of Na in the tunnel might presage ionic mobility for this material.

## 1. Chemical context

Alkali transition-metal phosphates belonging to the alluaudite family constitute one of the most diverse and rich classes of minerals, and have been studied intensively over the last few years. Owing to their outstanding physico-chemical properties, these compounds have many potential applications in various fields, such as catalytic activity (Kacimi et al., 2005) and as promising cathodes for sodium-ion batteries through the presence of mobile cations located in the tunnels of the open three-dimensional framework (Huang et al., 2015). In their recent study, Huang et al. (2015) point out that the electrochemical performance is not only associated with morphology, but also with the electronic and crystalline structure.

Accordingly, a large number of alluaudite phases with alkali cations in the tunnels have been reported. Nevertheless, the presence of alkali metals in the tunnels of synthetic alluaudite phases is frequently accompanied by cationic distributions that lead to non-stoichiometric compositions, such as: $\left(\mathrm{Na}_{0.38}, \mathrm{Ca}_{0.31}\right) \mathrm{MgFe}_{2}\left(\mathrm{PO}_{4}\right)_{3}$ ( Zid et al., 2005); $\mathrm{NaFe}_{3.67}\left(\mathrm{PO}_{4}\right)_{3}$ (Korzenski et al., 1998); $\mathrm{Cu}_{1.35} \mathrm{Fe}_{3}\left(\mathrm{PO}_{4}\right)_{3}$ (Warner et al., 1993); $\mathrm{K}_{0.53} \mathrm{Mn}_{2.37} \mathrm{Fe}_{1.24}\left(\mathrm{PO}_{4}\right)_{3}$ (Hidouri \& Ben Amara, 2011); $\mathrm{Na}_{1.79} \mathrm{Mg}_{1.79} \mathrm{Fe}_{1.21}\left(\mathrm{PO}_{4}\right)_{3}$ (Hidouri et al., 2003); $\mathrm{Na}_{1.50} \mathrm{Mn}_{2.48^{-}}$ $\mathrm{Al}_{0.85}\left(\mathrm{PO}_{4}\right)_{3}$ (Hatert, 2006); $\mathrm{Na}_{1-x} \mathrm{Li}_{x} \mathrm{MnFe}_{2}\left(\mathrm{PO}_{4}\right)_{3}$ where $x=$

[Symmetry codes: (i) $x+\frac{1}{2}, y+\frac{1}{2}, z$; (ii) $-x+\frac{3}{2}, y+\frac{1}{2},-z+\frac{1}{2}$; (iii) $-x+\frac{3}{2}$, $-y+\frac{3}{2},-z+1$; (iv) $-x+\frac{3}{2},-y+\frac{3}{2},-z$; (v) $-x+1,-y+1,-z$; (vi) $-x+1$, $y,-z+\frac{1}{2}$; (vii) $x,-y+1, z+\frac{1}{2}$; (viii) $x-\frac{1}{2},-y+\frac{3}{2}, z-\frac{1}{2}$; (ix) $-x+2, y$, $-z+\frac{3}{2} ;(x)-x+2,-y+1,-z+1 ;\left(\right.$ xi) $x+\frac{1}{2},-y+\frac{1}{2}, z+\frac{1}{2} ;($ (xii $)-x+\frac{3}{2}$, $-y+\frac{1}{2},-z+1$; (xiii) $x,-y+1, z-\frac{1}{2}$.]
$0,0.25,0.50$, and 0.75 (Hermann et al., 2002). As part of our study on alluaudite-related phosphates (Bouraima et al., 2015; Assani et al., 2011), we report the synthesis and the crystal structure of a new sodium, zinc and iron-based non-stoichiometric phosphate, namely $\mathrm{Na}_{1.67} \mathrm{Zn}_{1.67} \mathrm{Fe}_{1.33}\left(\mathrm{PO}_{4}\right)_{3}$.

## 2. Structural commentary

The alluaudite structure of the title compound crystallizes in the monoclinic space group $C 2 / c$, with $Z=4$. The principal building units of the crystal structure are represented in Fig. 1.

Figure 2
A view along the $b$ axis of a sheet resulting from chains connected by vertices of $\mathrm{PO}_{4}$ tetrahedra.

Figure 3
A stack of layers perpendicular to the $b$ axis, showing small tunnels along the [201] direction.

Refinement of the occupancy fractions, bond-valence analysis based on the formula proposed by Brown \& Altermatt (1985) and the required electrical neutrality of the structure lead to the formula $\mathrm{Na}_{1.67} \mathrm{Zn}_{1.67} \mathrm{Fe}_{1.33}\left(\mathrm{PO}_{4}\right)_{3}$ for the title compound. The mixed Fe 1 and Zn 1 atoms are located at the general position $8 f$ with $\mathrm{Fe}^{3+} / \mathrm{Zn}^{2+}$ occupancy fractions of 0.668 (3)/ 0.332 (3), and form a highly distorted $\left[(\mathrm{Fe} 1 / \mathrm{Zn} 1) \mathrm{O}_{6}\right]$ octahedral group, with $\mathrm{Fe}^{3+} / \mathrm{Zn}^{2+}-\mathrm{O}$ bond lengths ranging from 1.951 (1) to 2.209 (1) A . The Zn 2 atom is surrounded by six oxygen atoms, building a slightly distorted octahedron with an average $\mathrm{Zn} 2-\mathrm{O}$ bond length of 2.153 (1) $\AA$.

The crystal structure of this phosphate compound consists of infinite kinked chains of two edge-sharing $\left[\mathrm{Fe} 1 / \mathrm{Zn} 1 \mathrm{O}_{6}\right.$ ] octahedra leading to the formation of $\left[(\mathrm{Fe} 1, \mathrm{Zn} 1)_{2} \mathrm{O}_{10}\right]$ dimers that are connected by a common edge to $\left[\mathrm{Zn} 2 \mathrm{O}_{6}\right]$ octahedra, as shown in Fig. 2. These chains are linked by $\mathrm{PO}_{4}$ tetrahedral groups, forming a stack of sheets perpendicular to [010] and alternating with sodium layers, as shown in Fig. 3, which reveal small tunnels along the [201] direction. The three-dimensional framework also encloses two types of large tunnels, in which the $\mathrm{Na}^{+}$cations reside, as shown in Fig. 4. The site $4 e$ centred on the first tunnel is partially occupied by Na 1 [0.332 (3)], whereas Na 2 occupies site $4 a$ centred on the second tunnel. Each sodium atom is surrounded by eight oxygen atoms with $\mathrm{Na} 1-\mathrm{O}$ and $\mathrm{Na} 2-\mathrm{O}$ bond lengths in the ranges 2.448 (1)2.908 (2) $\AA$, and 2.324 (1) -2.901 (1) $\AA$, respectively. The displacement ellipsoids of the partially occupied atom Na 1 are rather larger than those of the rest of the atoms. Most probably this is due to the size of the channels, which allows atom

Figure 4

Na 1 to have more freedom. The disorder of Na in the tunnel may presage ionic mobility for this material.

## 3. Synthesis and crystallization

Single crystals of $\mathrm{Na}_{1.67} \mathrm{Zn}_{1.67} \mathrm{Fe}_{1.33}\left(\mathrm{PO}_{4}\right)_{3}$ were synthesised by conventional solid-state reaction (Girolami et al., 1999). The nitrate-based sodium, zinc and iron precursors, in addition to the $85 \mathrm{wt} \% \mathrm{H}_{3} \mathrm{PO}_{4}$ were taken in proportions corresponding to the molar ratio $\mathrm{Na}: \mathrm{Zn}: \mathrm{Fe}: \mathrm{P}=2: 2: 1: 3$. The resulting reaction mixture was ground in an agate mortar and progressively heated in a platinum crucible to the melting temperature of 1135 K . The melted product was cooled at a rate of $5 \mathrm{~K} / \mathrm{h}$. The product was obtained as transparent brown crystals corresponding to the title phosphate.

## 4. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. Refinements of the site-occupancy factors of the metal site $8 f$ revealed the ratio of $\mathrm{Fe} 1: \mathrm{Zn} 1=$ 0.668 (3):0.332 (3), whereas the the occupancy fraction of Na 1 was constrained to that of Zn 1 in order to maintain electrical neutrality. The highest peak and the deepest hole in the final difference Fourier map are at 0.72 and $0.40 \AA$ from O1 and Zn 2 , respectively.

## Acknowledgements

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Reflections were merged by SHELXL according to the crystal class for the calculation of statistics and refinement.
_reflns_Friedel_fraction is defined as the number of unique Friedel pairs measured divided by the number that would be possible theoretically, ignoring centric projections and systematic absences.
