The iron molybdate $\mathrm{NaMgFe}\left(\mathrm{MoO}_{4}\right)_{3}$ \{sodium magnesium iron(III) tris[molybdate( VI$)]$ \} has been synthesized by the flux method. This compound is isostructural with $\alpha-\mathrm{NaFe}_{2}\left(\mathrm{MoO}_{4}\right)_{3}$ and crystallizes in the triclinic space group $P \overline{1}$. Its structure is built up from $[\mathrm{Mg}, \mathrm{Fe}]_{2} \mathrm{O}_{10}$ units of edge-sharing $[\mathrm{Mg}, \mathrm{Fe}] \mathrm{O}_{6}$ octahedra which are linked to each other through the common corners of $\left[\mathrm{MoO}_{4}\right]$ tetrahedra. The resulting anionic three-dimensional framework leads to the formation of channels along the [101] direction in which the $\mathrm{Na}^{+}$cations are located.

## 1. Chemical context

Iron molybdates have been subject to very intensive research as a result of their numerous applications including as catalysts (Tian et al., 2011), multiferroic properties and more recently as a possible positive electrode in rechargeable batteries (Sinyakov et al., 1978; Mączka et al., 2011; Devi \& Varadaraju, 2012). In these materials, the anionic framework is constructed from $\mathrm{MoO}_{4}$ tetrahedra linked to the iron coordination polyhedra, leading to a large variety of crystal structures with a high capacity for cationic and anionic substitutions.

Until now, a total of six orthomolybdate compounds have been reported in the $\mathrm{Na}-\mathrm{Fe}-\mathrm{Mo}-\mathrm{O}$ system: $\mathrm{Na} 9 \mathrm{Fe}\left(\mathrm{MoO}_{4}\right)_{6}$ (Savina et al., 2013); $\mathrm{NaFe}\left(\mathrm{MoO}_{4}\right)_{2}$ (Klevtsova, 1975); $\alpha-\mathrm{NaFe}_{2}\left(\mathrm{MoO}_{4}\right)_{3}, \quad \beta-\mathrm{NaFe}_{2}\left(\mathrm{MoO}_{4}\right)_{3} \quad$ and $\mathrm{Na}_{3} \mathrm{Fe}_{2}\left(\mathrm{MoO}_{4}\right)_{3}$ (Muessig et al., 2003); $\mathrm{NaFe}_{4}\left(\mathrm{MoO}_{4}\right)_{5}$ (Ehrenberg et al., 2006). Their structures are described in terms of three-dimensional networks of isolated $\left[\mathrm{MoO}_{4}\right]$ tetrahedra and $\left[\mathrm{FeO}_{6}\right]$ octahedra. The sodium and mixed-valence iron molybdate $\mathrm{NaFe}_{2}\left(\mathrm{MoO}_{4}\right)_{3}$ exhibits two polymorphs, both crystallizing in the triclinic system. The low-temperature $\alpha$-phase changes irreversibly at high temperature into a $\beta$-phase. In addition to these orthomolybdate compounds, another phase with the formula $\mathrm{Na}_{3} \mathrm{Fe}_{2} \mathrm{Mo}_{5} \mathrm{O}_{16}$ and with layers of $\mathrm{Mo}_{3} \mathrm{O}_{13}$ units consisting of $\left[\mathrm{MoO}_{6}\right]$ octahedra has been synthesized and characterized (Bramnik et al., 2003). In addition, Kozhevnikova \& Imekhenova (2009) have investigated the $\mathrm{Na}_{2} \mathrm{MoO}_{4}{ }^{-}$ $M \mathrm{MoO}_{4}-\mathrm{Fe}_{2}\left(\mathrm{MoO}_{4}\right)_{3}$ system $(M=\mathrm{Mg}, \mathrm{Mn}, \mathrm{Ni}, \mathrm{Co})$ and have attributed the Nasicon-type structure with space group $R \overline{3} c$ (Kotova \& Kozhevnikova, 2003; Kozhevnikova \& Imekhenova, 2009) to the phase of variable composition $\mathrm{Na}_{(1-x)} M_{(1-x)} \mathrm{Fe}_{(1+x)}\left(\mathrm{MoO}_{4}\right)_{3}$. More recently, $\mathrm{NaNiFe}\left(\mathrm{MoO}_{4}\right)_{3}$ and $\mathrm{NaZnFe}\left(\mathrm{MoO}_{4}\right)_{3}$ (Mhiri et al., 2015) were found to be isostructural to $\beta-\mathrm{NaFe}_{2}\left(\mathrm{MoO}_{4}\right)_{3}$ and to have a good ionic conductivity with low activation energy, close to those of Nasicon-type compounds with similar formula such as $A \mathrm{Zr}_{2}\left(\mathrm{PO}_{4}\right)_{3}(A=\mathrm{Na}, \mathrm{Li})$. As an extension of the previous work, we report here on the synthesis and characterization by

## 2. Structural commentary

The title $\mathrm{NaMgFe}\left(\mathrm{MoO}_{4}\right)_{3}$ structure is based on a threedimensional framework of $[\mathrm{Mg}, \mathrm{Fe}]_{2} \mathrm{O}_{10}$ units of edge-sharing $[\mathrm{Mg}, \mathrm{Fe}] \mathrm{O}_{6}$ octahedra, connected to each other through the common corners of $\left[\mathrm{MoO}_{4}\right]$ tetrahedra. All $\left[\mathrm{Mg}, \mathrm{Fe}_{2} \mathrm{O}_{10}\right.$ units are parallel to [1 $\overline{1} 0]$ (Fig. 1). In this structure, two types of layers $(A$ and $B)$, similar to those observed in $\alpha-\mathrm{NaFe}_{2}\left(\mathrm{MoO}_{4}\right)_{3}$, are aligned parallel to (110) with the sequence $-A-B-B^{\prime}-A-B-B^{\prime}-$ and stacked along [001]. $B^{\prime}$ layers are obtained from $B$ by an inversion centre located on the $A$ planes (Fig. 2). The resulting anionic three-dimensional framework leads to the formation of channels along [101] in which the sodium ions are located (Fig. 3).

Computer programs: CAD-4 EXPRESS (Enraf-Nonius, 1994), XCAD4 (Harms \& Wocadlo, 1995), SIR92 (Altomare et al., 1993), SHELXL2014/7 (Sheldrick, 201), DIAMOND (Brandenburg \& Putz, 1999) and WinGX publication routines (Farrugia, 2012).

In the title structure, all atoms are located in general positions. The three crystallographically different molybdenum atoms have a tetrahedral coordination with $\mathrm{Mo}-\mathrm{O}$ distances between 1.715 (3) and $1.801(2) \AA$. The mean distances $(\mathrm{Mo} 1-\mathrm{O}=1.762, \mathrm{Mo} 2-\mathrm{O}=1.766$ and $\mathrm{Mo} 3-\mathrm{O}=1.760 \AA$ ) are in good accordance with those usually observed in molybdates (Abrahams et al., 1967; Harrison \& Cheetham, 1989; Smit et al., 2006). The [Mg,Fe]-O distances and the cis $\mathrm{O}-[\mathrm{Mg}, \mathrm{Fe}]-\mathrm{O}$ angles in the $\left[\mathrm{Mg}, \mathrm{Fe}_{2} \mathrm{O}_{10}\right.$ units range from 2.003 (3) to 2.099 (3) $\AA$ and from 81.2 (1) to $177.8(1)^{\circ}$, respectively. This dispersion reflects a slight distortion of the $[\mathrm{Mg}, \mathrm{Fe}] \mathrm{O}_{6}$ octahedra. The average distances $[\mathrm{Mg}, \mathrm{Fe}] 1-\mathrm{O}=$ 2.059 and $[\mathrm{Mg}, \mathrm{Fe}] 2-\mathrm{O}=2.013 \AA$ lie between the values of $1.990 \AA$ observed for six-coordinated $\mathrm{Fe}^{3+}$ in $\mathrm{LiFe}\left(\mathrm{MoO}_{4}\right)_{2}$ (van der Lee et al. 2008) and $2.072 \AA$ reported for $\mathrm{Mg}^{2+}$ with the same coordination in $\mathrm{NaMg}_{3} \mathrm{Al}\left(\mathrm{MoO}_{4}\right)_{5}$ (Hermanowicz et al., 2006). This result is related to the disordered distribution of $\mathrm{Fe}^{3+}$ and $\mathrm{Mg}^{2+}$ in both sites. Assuming sodium-oxygen distances below $3.13 \AA$ (Donnay \& Allmann, 1970), the Na site is surrounded by five oxygen atoms (Fig. 4).

## 3. Synthesis and crystallization

Crystals of the title compound were grown in a flux of sodium dimolybdate $\mathrm{Na}_{2} \mathrm{Mo}_{2} \mathrm{O}_{7}$ with an atomic ratio $\mathrm{Na}: \mathrm{Mg}: \mathrm{Fe}: \mathrm{Mo}=$ 5:1:1:7. Appropriate amounts of the starting reactants $\mathrm{NaNO}_{3}$, $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Fe}\left(\mathrm{NO}_{3}\right)_{3} \cdot 9 \mathrm{H}_{2} \mathrm{O}$ and $\left(\mathrm{NH}_{4}\right)_{6} \mathrm{Mo}_{7} \mathrm{O}_{24} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ were dissolved in nitric acid and the resulting solution was
evaporated to dryness. The dry residue was then placed in a platinum crucible and slowly heated in air up to 673 K for 24 h to remove $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{NH}_{3}$. The mixture was ground in an agate mortar, melted for 2 h at 1123 K and then cooled to room temperature at a rate of $5 \mathrm{~K} \mathrm{~h}^{-1}$. Crystals without regular shape were separated from the flux by washing in boiling water.

## 4. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. The application of the direct methods revealed two sites, labeled $M(1)$ and $M(2)$, statistically occupied by the $\mathrm{Fe}^{3+}$ and $\mathrm{Mg}^{2+}$ ions. This distribution was supported by the $M 1-\mathrm{O}$ and $M 2-\mathrm{O}$ distances which are between the classical values for pure $\mathrm{Mg}-\mathrm{O}$ and $\mathrm{Fe}-\mathrm{O}$ bonds. Succeeding difference Fourier synthesis led to the positions of all the remaining atoms.

Extinction coefficient: 0.0074 (5)

## Special details

Geometry. All esds (except the esd in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. Refinement of $\mathrm{F}^{2}$ against ALL reflections. The weighted R -factor wR and goodness of fit S are based on $\mathrm{F}^{2}$, conventional R-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>2 \operatorname{sigma}\left(\mathrm{~F}^{2}\right)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on $\mathrm{F}^{2}$ are statistically about twice as large as those based on F , and R - factors based on ALL data will be even larger.
