# Crystal structure of a second polymorph of tricarbonyl( $N$-methylpyridine-2-carboxamide$\kappa^{2} N^{1}, O$ )(thiocyanato- $\kappa N$ )rhenium (I) 

Krzysztof Lyczko*

Institute of Nuclear Chemistry and Technology, Dorodna 16, 03-195 Warsaw, Poland. *Correspondence e-mail: k.lyczko@ichtj.waw.pl

A new polymorph of the title compound, $\left[\operatorname{Re}(\mathrm{NCS})\left(\mathrm{C}_{7} \mathrm{H}_{8} \mathrm{~N}_{2} \mathrm{O}\right)(\mathrm{CO})_{3}\right]$, crystallizing in the space group $P 2_{1} / n$, has been obtained and structurally characterized by the experiment and DFT calculations. In this complex, the rhenium(I) cation is octahedrally coordinated by three carbonyl groups in a facial configuration, the $\mathrm{N}, \mathrm{O}$-bidentate N -methylpyridine-2-carboxamide ligand and the N -bonded thiocyanate anion. Neighbouring molecules are linked into a three-dimensional network by intermolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ interactions.

## 1. Chemical context

Tricarbonylrhenium(I) complexes in the ' $2+1$ ' system (with one bidentate and one monodentate ligand) are still widely studied because of their interesting photophysical and photochemical properties (Pizarro et al., 2015; Zhao et al., 2015; Portenkirchner et al., 2015) and possible applications in medicine (Ma et al., 2014; Wähler et al., 2014; Collery et al., 2015). Recently, a few tricarbonyl compounds of rhenium(I) with the bidentate $\mathrm{N}, \mathrm{O}$-donor ligand N -methylpyridine-2carboxyamide $\left[L H(M e)_{\mathrm{NO}}\right]$ and with different monodentate ligands being either an anion $\left(\mathrm{Cl}^{-}, \mathrm{Br}^{-}, \mathrm{I}^{-}\right.$and $\left.\mathrm{SCN}^{-}\right)$or a neutral molecule [imidazole (Him) and 3,5-dimethylpyrazole (Hdmpz)] have been characterized, among others, by X-ray crystallographic analysis (Lyczko et al., 2015). The first polymorph of the title complex $\left[\operatorname{Re}(\mathrm{CO})_{3}\left(L \mathrm{H}(\mathrm{Me})_{\mathrm{NO}}\right) \mathrm{NCS}\right]$ to be reported (Lyczko et al., 2015) has triclinic symmetry and crystallizes in the space group $P \overline{1}$.

In the current study, a second polymorph of this compound crystallizing in the monoclinic space group $P 2_{1} / n$ has been obtained and its structure is reported here, including a comparison of the triclinic and monoclinic polymorphs.

Notes: ${ }^{(a)}$ DFT Calculations were carried out by means of GAUSSIAN09 software (Frisch et al., 2009) using the B3LYP functional and the LANL2DZ basis set for the Re atom; ${ }^{(b)}$ data from Lyczko et al. (2015).

## 2. Structural commentary

The molecular structure of the monoclinic polymorph of the studied tricarbonylrhenium(I) complex with a bidentate ligand and a pseudohalide anion is presented in Fig. 1. The metal ion is surrounded in a slightly distorted octahedral coordination environment by six donor atoms, including three carbon atoms of the carbonyl groups, two nitrogen atoms and one oxygen atom. The three CO ligands occupy the facial positions of this octahedron. The $\mathrm{Re}-\mathrm{C}$ bond lengths are in the range 1.9028 (16) -1.9201 (16) A. The three remaining positions in the $f a c-\left[\operatorname{Re}(\mathrm{CO})_{3}\right]^{+}$core are occupied by one

Figure 1
The molecular structure of the title compound, with displacement ellipsoids for the non-H atoms drawn at the $50 \%$ probability level.
bidentate ligand and one monodentate ligand, which results in a so called ' $2+1$ ' system. $N$-methylpyridine- 2 -carboxyamide behaves in the complex as a neutral ligand and chelates the rhenium(I) ion by means of oxygen and nitrogen atoms with bond lengths of 2.1583 (10) and 2.1836 (13) $\AA$, respectively, forming a five-membered ring. The $\mathrm{N} 1-\mathrm{Re} 1-\mathrm{O} 4$ bite angle of $74.33(4)^{\circ}$ is typical for that type of chelate ring. The sixth coordination position of the metal ion is occupied by the N atom of the thiocyanate anion. The use of the $\mathrm{NCS}^{-}$ion in the reaction mixture together with an $L \mathrm{H}(\mathrm{Me})_{\text {NO }}$ ligand leads to the formation of a neutral complex. This pseudohalide ion, which can exhibit an ambidentate character acting with the central metal cation either by its sulfur or nitrogen atom, coordinates in the present complex through the N atom, which is generally typical for hard metal ions using the 'hard and soft acids and bases' (HSAB) concept. All of the structural parameters mentioned above are very similar to those previously reported for the triclinic polymorph of the title compound (see Table 1). The molecular structures of the two polymorphic forms are compared in Fig. 2.

It can be ruled out that the use of $\mathrm{AgBF}_{4}$ for precipitation of $\mathrm{Cl}^{-}$ions during the synthesis of the title complex (see Section 5) leads to the crystallization of its monoclinic polymorph, while the presence of $\mathrm{PF}_{6}{ }^{-}$anions, originating from the silver salt, contributes to the formation of its triclinic form (Lyczko et al., 2015).

## 3. DFT calculations

The bond lengths and angles for the present complex originating from the crystal structure determination are in good agreement with DFT calculations (see Table 1) performed by means of the B3LYP functional and three different basis sets for non-metallic atoms (the Re atom was described by the LANL2DZ basis set) using the GAUSSIAN09 software (Frisch et al., 2009). In most cases, the differences between

Figure 2
Graphical representations showing the overlays of the molecular structures obtained for the $\left[\operatorname{Re}(\mathrm{CO})_{3}\left(L \mathrm{H}(M e)_{\mathrm{NO}}\right) \mathrm{NCS}\right]$ complex from diffraction experiments and DFT calculations. The monoclinic form is blue, the triclinic form green and the DFT-optimized structure [B3LYP/ LANL2DZ,6-311 G++(d,p)] is red.
experimentally and theoretically determined atomic distances are no larger than $0.03 \AA$. In only a few cases, this difference larger than $0.03 \AA$, with the largest difference being about $0.08,0.07$ or $0.06 \AA$ using the $6-31 \mathrm{G}(\mathrm{d}, \mathrm{p}), 6-31 \mathrm{G}++(\mathrm{d}, \mathrm{p})$ or $6-311 \mathrm{G}++(\mathrm{d}, \mathrm{p})$ basis sets, respectively, for the Re1-O4 bond length. The use of three different basis sets gave similar results. However, a slightly better correlation with the experiment can be observed by using the $6-311 \mathrm{G}++(\mathrm{d}, \mathrm{p})$ basis set. It is especially noticeable if the $\mathrm{C} 12-\mathrm{N} 3-\mathrm{Re} 1$ angle and the bond lengths involving the chelating atoms (Re1-N1 and $\mathrm{Re} 1-\mathrm{O} 4)$ are compared. The good agreement between the DFT-optimized and the experimentally determined structures is illustrated in Fig. 2.

## 4. Supramolecular features

The molecular structure of both polymorphic forms of the $\left[\mathrm{Re}(\mathrm{CO})_{3}\left(\mathrm{LH}(\mathrm{Me})_{\mathrm{NO}}\right) \mathrm{NCS}\right]$ complex are very similar, but

Figure 3
Fragment of the crystal structure of the title complex showing $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ hydrogen-bonding interactions as dashed lines.

Table 2
Hydrogen-bond geometry $\left(\AA,{ }^{\circ}\right)$.

| $D-\mathrm{H} \cdots A$ | $D-\mathrm{H}$ | $\mathrm{H} \cdots A$ | $D \cdots A$ | $D-\mathrm{H} \cdots A$ |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{~N} 2-\mathrm{H} 2 \cdots \mathrm{~S} 1^{\mathrm{i}}$ | $0.84(2)$ | $2.57(2)$ | $3.3642(14)$ | $158.0(19)$ |
| $\mathrm{C} 7-\mathrm{H} 7 \cdots \mathrm{~S} 1^{\mathrm{i}}$ | 0.95 | 2.90 | $3.8255(16)$ | 166 |
| $\mathrm{C} 10-\mathrm{H} 10 \mathrm{C} \cdots 1^{\mathrm{ii}}$ | 0.98 | 2.98 | $3.8445(17)$ | 148 |

Symmetry codes: (i) $x+\frac{1}{2},-y+\frac{3}{2}, z-\frac{1}{2}$; (ii) $x+1, y, z$.
their crystal structures display different packing features. In the crystal structure of the monoclinic polymorph, the molecules are held together by $\mathrm{N} 2-\mathrm{H} 2 \cdots \mathrm{~S} 1$ hydrogen bonds [3.3642 (14) $\AA$ ] and two other weaker interactions [C7$\mathrm{H} 7 \cdots \mathrm{~S} 1,3.8255$ (16) $\AA$ and $\mathrm{C} 10-\mathrm{H} 10 \mathrm{C} \cdots \mathrm{S} 1,3.8445$ (17) $\AA$; Table 2, Fig. 3). In turn, the molecular packing in the triclinic form is characterized by the presence of intermolecular hydrogen bonds of 3.335 (3) $\AA(\mathrm{N} 2-\mathrm{H} 2 \cdots \mathrm{~S} 1)$, 3.743 (4) $\AA$ (C6-H6 $\cdots \mathrm{S} 1$ ) and 3.921 (4) $\AA(\mathrm{C} 7-\mathrm{H} 7 \cdots \mathrm{~S} 1)$ (Lyczko et al., 2015). The shortest distances between neighbouring $S$ atoms of the thiocyanate ions $[7.033$ (1) and 7.175 (1) $\AA$ ] in the monoclinic polymorph are much longer than the respective $S \cdots S$ contacts $[4.736$ (2) $\AA$ ] in the triclinic form.

## 5. Database survey

The triclinic polymorph of the title complex has been presented recently (Lyczko et al., 2015). Only a few crystal structures in which the thiocyanate ion coordinates to a tricarbonylrhenium(I) core can be found in the Cambridge Structural Database (Groom et al., 2016) to date. In all these complexes, the thiocyanato group interacts with the central metal atom in an $N$-bonded mode. The $\mathrm{Re}-\mathrm{N}_{(\mathrm{NCS})}$ bond lengths in both polymorphs of $\left[\mathrm{Re}(\mathrm{CO})_{3}\left(\mathrm{LH}(\mathrm{Me})_{\mathrm{NO}}\right) \mathrm{NCS}\right]$ [2.1275 (13) $\AA$ for the monoclinic form (this work) and 2.117 (3) $\AA$ for the triclinic form (Lyczko et al., 2015)] are similar to other such bonds observed in $\left[\operatorname{Re}(\mathrm{CO})_{3}(\right.$ bi$\left.\left.\operatorname{py}\left(\mathrm{CH}_{3}\right)(\mathrm{COOH})\right) \mathrm{NCS}\right][2.125(3) \AA$, Cavigli et al., 2016], $\left[\operatorname{Re}(\mathrm{CO})_{3}(t \mathrm{Bu}-\mathrm{DAB}) \mathrm{NCS}\right][2.115(1) \AA$ A; Grupp et al., 2014], $\left[\operatorname{Re}(\mathrm{CO})_{3}(\right.$ bipy-PdTPP)NCS] [2.132 (9) Å; Schneider et al., 2011], [ $\left.\operatorname{Re}(\mathrm{CO})_{3}(\mathrm{Pr}-\mathrm{DAB}) \mathrm{NCS}\right][2.115$ (7) $\AA$; Rodríguez et al., 2005], $\left[\operatorname{Re}(\mathrm{CO})_{3}(\right.$ bipy $\left.) \mathrm{NCS}\right][2.123(4)$ and $2.129(4) \AA$; Rodríguez et al., 2005] or $\left[\operatorname{Re}(\mathrm{CO})_{3}\left(\mathrm{NCS}_{3}\right]\left(\mathrm{NEt}_{4}\right)_{2}[2.112-\right.$ 2.145 (10) Å; Abram et al., 1996].

## 6. Synthesis and crystallization

The title complex was synthesized by refluxing a methanol solution $(5.0 \mathrm{ml})$ of $\operatorname{Re}(\mathrm{CO})_{5} \mathrm{Cl}(0.050 \mathrm{~g}, 0.138 \mathrm{mmol})$ with $N$ -methylpyridine-2-carboxyamide $(0.30 \mathrm{~g}, \quad 0.220 \mathrm{mmol})$ and KSCN $(0.020 \mathrm{~g}, 0.206 \mathrm{mmol})$ after previous precipitation of AgCl by means of $\mathrm{AgBF}_{4}(0.027 \mathrm{~g}, 0.139 \mathrm{mmol})$, similar to the method described earlier (Lyczko et al., 2015). The volume of this solution was decreased in a desiccator under reduced pressure. A yellow crystalline material was obtained after storing the solution for a few weeks in a refrigerator. Crystallization yield: 0.022 g ( $34.4 \%$ ). Elemental analysis calcu-

## 7. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 3. H atoms bonded to C atoms were inserted in calculated positions with $\mathrm{C}-\mathrm{H}=0.98$ (methyl) or $0.95 \AA$ (aromatic) and refined isotropically using a riding model with $U_{\text {iso }}(\mathrm{H})$ equal to $1.5 U_{\text {eq }}(\mathrm{C})$ or $1.2 U_{\text {eq }}(\mathrm{C})$ for methyl and aromatic H atoms, respectively. In turn, the H atom of the NH pair was located in a difference Fourier map and its position was freely refined.

$k=-18 \rightarrow 18$
$l=-17 \rightarrow 17$

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.011$
$w R\left(F^{2}\right)=0.025$
$S=1.11$
4060 reflections
186 parameters
0 restraints

Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.011$
$w R\left(F^{2}\right)=0.025$
$S=1.11$
4060 reflections
186 parameters
0 restraints

```
Hydrogen site location: mixed
    H atoms treated by a mixture of independent
        and constrained refinement
\(w=1 /\left[\sigma^{2}\left(F_{o}^{2}\right)+(0.0082 P)^{2}+0.8572 P\right]\)
    where \(P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3\)
\((\Delta / \sigma)_{\max }=0.005\)
\(\Delta \rho_{\text {max }}=0.42 \mathrm{e}^{\AA^{-3}}\)
\(\Delta \rho_{\text {min }}=-0.51 \mathrm{e} \AA^{-3}\)
```

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
