1,8 -Cineole is an abundant natural product that has the potential to be transformed into other building blocks that could be suitable alternatives to petroleum-based chemicals. Monohydroxylation of 1,8-cineole can potentially occur at eight different carbon sites around the bicyclic ring system. Using cytochrome P450 monooxygenase CYP101J2 from Sphingobium yanoikuyae B2, the hydroxylation can be regioselectively directed at the C atom adjacent to the methyl-substituted quaternary bridgehead atom of 1,8 -cineole. The unambiguous location of the hydroxyl functionality and the stereochemistry at this position was determined by X-ray crystal analysis. The monohydroxylated compound derived from this microorganism was determined to be (1S)-2a-hydroxy-1,8-cineole (trivial name) or ( $1 S, 4 R, 6 S$ )-1,3,3-trimethyl-2-oxabi-cyclo[2.2.2]octan-6-ol (V) (systematic), $\mathrm{C}_{10} \mathrm{H}_{18} \mathrm{O}_{2}$. In the solid state this compound exhibits an interesting $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen-bonding motif.

## 1. Chemical context

The terpenoid compound commonly known as 1,8 -cineole, or less easily identified using systematic nomenclature as $1,3,3-$ trimethyl-2-oxabicyclo[2.2.2]octane (I) (Fig. 1), is a key component of the leaf oil from eucalypts and is also found in a variety of plant types, such as sage, thyme and fruit extracts, albeit in lower quantities (Fig. 1). Its natural abundance makes it a suitable bio-derived feedstock from which other useful chemical building blocks could be accessed and used as an alternative to petrochemical based-materials. Although continued research into the chemical and biochemical trans-

Figure 1

Trivial and systematic naming and atom numbering used for compound (I).
formation of 1,8-cineole (I) is being directed towards accessing high quality and commercial quantities of these derivatives, the naming of these products by using non-systematic nomenclature, coupled with the chiral nature of these products has created inconsistencies and made it challenging to compare data of these derivatives in the literature. To address this Azerad (2014) recently published an extremely useful review article capturing all the oxidation products of 1,8-cineole (I) by providing trivial and systematic names along with characterization data (i.e. melting point, optical rotation and proton and carbon NMR spectroscopic information).

In continuing our research activities on the biocatalytic mono-hydroxylation of 1,8 -cineole (I) at the C atom adjacent to the quaternary C 1 bridgehead atom (i.e. labelled 6 or 7 following IUPAC rules) four possible stereoisomers [Fig. 2, compounds (II), (III), (IV) and (V)] could be formed. However, there is no current crystallographic information of these pure materials to support these assignments. Knowing the inconsistencies with the nomenclature of these compounds and to gain a better understanding of how to control the regio-

and stereo-chemistry at the different sites around the 1,8 cineole bicyclic ring system, we sought confirmation of the absolute configuration by undertaking X-ray crystallographic studies.

## 2. Structural commentary

Suitable crystals for X-ray diffraction were prepared by the slow diffusion of petroleum ether into a solution of the compound dissolved in ethyl acetate. The X-ray crystal structure of the purified mono-hydroxylated 1,8-cineole (V) Fig. 3) was solved in the $P 2_{1}$ space group and revealed the location of the hydroxyl group to be in the 6 position (IUPAC) (Fig. 1). The absolute configuration was determined by the method of Parsons et al. (2013) and confirmed the proposed stereochemistry (i.e. structure (V) see above, Fig. 2).

(V)

The presence of the axial hydroxyl substituent in (V) breaks the crystallographic symmetry of the parent 1,8 -cineole (I), with $P 2_{1} / m$ space group (Bond \& Davies, 2001), resulting in a slight twisting of the molecular framework as shown by the torsion angle $\mathrm{C} 1-\mathrm{O} 2-\mathrm{C} 7-\mathrm{C} 4$ of $-12.8(2)^{\circ}$ and is presumably steric in origin. For the related 1,8-cineole-5,6-diol, three

Figure 3
Molecular structure of ( $1 S, 4 R, 6 S$ )-1,3,3-trimethyl-2-oxabicyclo[2.2.2]-octan-6-ol (V) with non-H atoms represented by $50 \%$ displacement ellipsoids and H atoms as spheres of arbitrary size.

Table 1
Hydrogen-bond geometry ( $\AA^{\circ},{ }^{\circ}$ ).

| $D-\mathrm{H} \cdots A$ | $D-\mathrm{H}$ | $\mathrm{H} \cdots A$ | $D \cdots A$ | $D-\mathrm{H} \cdots A$ |
| :--- | :--- | :--- | :--- | :--- |
| $\mathrm{O} 1-\mathrm{H} 1 \cdots \mathrm{O}^{\mathrm{i}}$ | $0.80(3)$ | $1.97(3)$ | $2.7530(19)$ | $170(3)$ |

Symmetry code: (i) $-x+1, y-\frac{1}{2},-z+1$.
of the four possible diastereoisomers have been structurally characterized and only the one with the $6 \alpha$ hydroxyl group showed a similar distortion (Farlow et al., 2013).

## 3. Supramolecular features

Individual molecules of (V) are connected by $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds between the hydroxyl and ether moieties (Table 1) and form spiral chains parallel to the $b$ axis (Fig. 4).

## 4. Database survey

A search of the Cambridge Structural Database (V5.38; Groom et al., 2016) for the 1,3,3-trimethyl-2-oxabicyclo[2.2.2]octane (cineole) skeleton gave the parent structure (I) (ref code MOFPAY; Bond \& Davies, 2001) and the oxidation products, 5,6-dihydroxycineole (three steroisomers: ref codes DIFJAF, DIFJEJ and DIFJIN; Farlow et al., 2013), 6-(1,3-dioxolan-2-yl)-5-ketocineole and 5-(1,3-dioxolan-2-yl)-6ketocineole (ref codes DIFHOR and DIFHUX; Farlow et al., 2013).

## 5. Synthesis and crystallization

1,8-Cineole (I) was mono-hydroxylated using a recombinant Escherichia coli whole-cell fed-batch process using CYP101J2 in combination with suitable redox partner proteins from $S$. yanoikuyae B2 to provide a major product (Unterweger, 2016). The isolated material was further purified by recrystallization from diethyl ether/petroleum ether to afford white needles. The melting point (this work m.p. 371.2-371.8 K, lit. m.p. 371-372 K (Carman et al., 1986), 370, 370, 369, 368, 371372, 371-372, 371-372 369-372, 372 and 370 K as cited in Azerad (2014)) and ${ }^{1} \mathrm{H}$ NMR spectrum are in agreement with

Figure 4
Ball-and-stick representation of a hydrogen-bonded chain of molecules of (V). Only selected H atoms are shown and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ contacts are indicated as dashed bonds.

Computer programs: CrysAlis PRO (Rigaku OD, 2015), SHELXS97 (Sheldrick, 2015), SHELXL2016 (Sheldrick, 2015), X-SEED (Barbour, 2001) and publCIF (Westrip, 2010).
cited literature values (Azerad, 2014) for either compound (IV) and/or (V). Optical rotation \{this work $[\mathrm{a}]_{\mathrm{D}}+32.0$ (c 1.3, $\mathrm{EtOH})$, lit $[\mathrm{a}]_{\mathrm{D}}+31.9$ (c 1.3, EtOH)\}. The experimental data for the current material produced from the biotransformation of cineole is well aligned with one set of literature data (Carman et al., 1986).

## 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. H atoms potentially involved in hydrogen-bonding interactions were located by difference methods and were freely refined. Other H atoms were included in the refinement at calculated positions with $\mathrm{C}-\mathrm{H}=$ $0.95-0.98 \AA$ and treated as riding with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$ or $1.52 U_{\text {eq }}(\mathrm{O}$ or methyl C).

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
