#### Abstract

${ }^{\mathrm{a}}$ J. Heyrovsky Institute of Physical Chemistry, Academy of Sciences of the Czech Republic, Dolejškova 2155/3, 18223 Prague 8, Czech Republic, 'buniversity of Chemistry and Technology, Technická 5, 16628 Prague 6, Czech Republic,  *Correspondence e-mail: jiri.ludvik@jh-inst.cas.cz

The asymmetric unit of the title compound, $\mathrm{C}_{12} \mathrm{H}_{15} \mathrm{NO}$, comprises two symmetry-independent molecules which differ mainly in the conformations of the tert-butyl groups. The molecules contain an essentially planar five-membered 3-pyrroline ring incorporating a carbonyl substituent (pyrrolinone) which forms part of an isoindolinone skeleton. The planarity of the pyrrole ring is compared to other structures with isoindolinone. There are only weak intra- and intermolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \pi$-electron-ring interactions in the crystal structure.

## 1. Chemical context

Orthophthalaldehyde (o-phthalaldehyde, OPA) is an aromatic dialdehyde bearing two electron-withdrawing carbonyl groups in positions 1 and 2 . The reaction scheme involving OPA, (I), shown in Fig. 1 comprises the main concurrent as well as consecutive reactions, which are consistent with the results obtained herein. The reactions of OPA with primary amines, which were carried out by Winter (1900) and Thiele \& Schneider (1909) for the first time, have been broadly applied for the synthesis of important heterocyclic compounds with biological relevance. A number of such reactions have been investigated recently and several structures of condensation products have been reported (DoMinh et al., 1977; Nan'ya et al., 1985; Takahashi et al., 1996, 2004, 2005; Takahashi \& Hatanaka, 1997). However, the reaction mechanism is still not fully understood. Determination of the products which would serve as a confirmation of the suggested reaction scheme (Fig. 1) is the reason for the present as well as for our previous studies (Donkeng Dazie, Liška \& Ludvík, 2016; Donkeng Dazie, Liška, Ludvík, Fábry \& Dušek, 2016; Donkeng Dazie et al., 2017).

The reason why a full understanding of the reaction mechanism is still lacking is the complexity of the abovementioned reactions, which are dependent on different variables. Our partly published electrochemical experiments have shown that the reaction kinetics, as well as the reaction products, depend on the primary amine which reacts with OPA, the reaction environment (solvent) and the proportion of the reactants (Donkeng Dazie, Liška \& Ludvík, 2016).

Figure 1
The reaction scheme for the synthesis of the title compound, (V).

Electrochemical monitoring has indicated the presence of side reactions, which result in a mixture of molecules of different molecular weights with different proportions of OPA and primary amine building blocks [ $c f$. the reaction of OPA with 2-aminoethanol (kolamine); see Urban et al. (2007a,b)].

The complexity of the reactions between primary amines and OPA is affected by the environment in which they take place. The reaction of OPA with aliphatic primary amines in aqueous solutions involves competition between the amines and water molecules as nucleophiles. Although water is a weaker nucleophile than primary amines, an enormous excess of water over primary amines may cause significant additional reactions, such as covalent hydration at the double bond of the carbonyl group and the following cyclization (Zuman, 2004) see compounds (II) and (III) in Fig. 1. The reaction of OPA with aliphatic primary amines represents a concurrent process (DoMinh et al., 1977). All attempts to isolate and identify the products of the reaction of OPA with primary amines in aqueous solutions were unsuccessful due to the number of reactions occurring and products, including the oligo- and polymeric ones (checked by thin-layer chromatography). In order to simplify the reaction media, diethyl ether as a nonaqueous organic solvent was used with the hope that some products might be obtained as crystals suitable for X-ray structure analysis.

Analogous to the reaction of OPA with isopropylamine (Donkeng Dazie, Liška, Ludvík, Fábry \& Dušek, 2016), the first step of the reaction with tert-butylamine results in a primary carbinolamine, (IV), the intermediate which further yields the title product, (V) (DoMinh et al., 1977). The title product, (V), as well as co-product (VI), namely ( $3 R^{*}, 1^{\prime} S^{*}, 3^{\prime} R^{*}$ )-3-( $1^{\prime}$-tert-butylamino- $1^{\prime} H, 3^{\prime} H$-benzo[ [] furan-3'-yl)-2-tert-butyl-2,3-dihydro-1 $H$-benzo $[c]$ pyrrol-1-one) were identified as the main products in solution by means of ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR analysis, as well as mass spectroscopy with electrospray ionization (ESI+). Compound (VI) was also crystal-

| $\mathrm{C} 1 B-\mathrm{C} 2 B-\mathrm{C} 3 B-\mathrm{C} 4 B-\mathrm{C} 5 B-\mathrm{C} 6 B$ | 119 | -0.0069 (14) | C5B |

lized and its structure has been determined previously (Donkeng Dazie et al., 2017).

The spectrometric results were confirmed unequivocally by the X-ray structure analysis of compound (V) (Fig. 2), as well as by the structure determination of (VI) (Donkeng Dazie et al., 2017). In addition to the confirmation of the presence of the products in solution after they had been resolved as crystals, the previous crystallographic studies of (VI) and 2-isopropyl-2,3-dihydro- $1 H$-isoindol-1-one (Donkeng Dazie, Liška, Ludvík, Fábry \& Dušek, 2016) were focused on the problem of planarity of the annelated pyrrole and furan rings.

The planarity of the pyrrole rings, which include two atoms close to $s p^{3}$-hybridized, was explained by propitious values of the inner angle in the regular pentagon of $108^{\circ}$, i.e. close to the ideal tetrahedral value of $109.54^{\circ}$. It turned out that the planarity is correlated on the $\mathrm{C}-\mathrm{N}$ bond lengths in the pyrrole fragment. Specifically, pyrrole rings with longer N $\mathrm{C}_{\text {carbonyl }}$ bond lengths which exceed $1.39 \AA$ tend to show better planarity than pyrrole rings with these shorter bond lengths (see Fig. 4 in the article by Donkeng Dazie, Liška, Ludvík, Fábry \& Dušek, 2016).

The structure of (VI) (Donkeng Dazie et al., 2017) contains pyrrole and furan rings as parts of isoindolinone and isobenzofuran rings, respectively. The planarity of the pyrrole ring is extremely distorted in this structure and deviates more from planarity than the furan ring in the same structure. This phenomenon can be explained by steric reasons due to the presence of a voluminous tert-butyl group. The distortion of the pyrrole ring can be provoked by repulsion of the parts of the isoindolinone and isobenzofuran rings which are close to each other. Therefore, the present structure determination is even more interesting because it offers a comparison of the

Figure 3
Two overlapped independent molecules provided by MolFit in PLATON (Spek, 2009).
distortion of the planarity of the pyrrole rings in the title structure with those in 2-tert-butyl-2,3-dihydro-1H-benzo $[c]$ -]pyrrol-1-one (Donkeng Dazie, Liška, Ludvík, Fábry \& Dušek, 2016) and ( $3 R^{*}, 1^{\prime} S^{*}, 3^{\prime} R^{*}$ )-3-( $1^{\prime}$-tert-butylamino- $1^{\prime} H, 3^{\prime} H$-ben-zo[c]furan-3'-yl)-2-tert-butyl-2,3-dihydro-1H-benzo[c]pyrrol-1-one, (VI) (Donkeng Dazie et al., 2017), i.e. with respective less and more voluminous substituents.

## 2. Synthesis and crystallization

The synthesis of (V) was carried out at laboratory temperature under an argon atmosphere and the isolation procedure was similar to that reported by Takahashi et al. (2004, 2005). Orthophthalaldehyde (OPA, 0.335 g ) was dissolved in diethyl ether ( $25 \mathrm{ml}, 0.1 \mathrm{~mol} \mathrm{l}^{-1}$ ) and tert-butylamine $(0.183 \mathrm{~g}, 264 \mu \mathrm{l}$ of the pure liquid compound) was added to the solution of OPA. The amounts of the reactants correspond to a 1:1 OPAamine stoichiometric ratio. The reaction mixture was stirred for 6 h . The solution was filtered and the ether was evaporated under reduced pressure. Two previously mentioned compounds, i.e. (V) and (VI), were identified in a light-yellow oily solution by ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR analysis, as well as mass spectroscopy. After a few days at room temperature, lightyellow crystals of (VI) of the size of several tenths of mm appeared. After half a year, other crystals appeared in the form of thin light-yellow needles which were as long as 2 cm . Their other dimensions were smaller than 0.1 mm . These crystals corresponded to the expected product, namely the title compound (V).

## 3. Structural commentary

The title compound comprises two symmetry-independent molecules ( $A$ and $B$ ) in the asymmetric unit (Fig. 2), the ring systems of which are approximately coplanar [dihedral angle between the planes $\left.=8.38(4)^{\circ}\right]$. The two molecules are conformationally similar but not identical. The function AutoMolFIT in PLATON (Spek, 2009) yielded the weighted and unit-weight r.m.s. fits for the non-H atoms as 1.437 and $0.952 \AA$, respectively. The main difference between the two independent molecules lies in the conformations within the tert-butyl substituent group (Fig. 3). These differences are reflected in the comparative values of the $\mathrm{C} 7 A / B-\mathrm{N} 1 A / B-$ $\mathrm{C} 9 A / B-\mathrm{C} 10 A / B$ torsion angles [151.25 (10) and $129.76(11)^{\circ}$, respectively].

Figure 4
The dependence of the extremal deviations from planarity, $\Delta_{\text {extrem }}(\AA)$, within the pyrrole core atoms of the isoindolinone system on the $\mathrm{N}-\mathrm{C}$ bond length in $\mathrm{N}-\mathrm{C} 8(=\mathrm{O})(\AA)$ (OriginLab, 2000). Black squares indicate the structures retrieved from the CSD, the red circle is 2 -isopropyl-2,3-dihydro-1H-isoindol-1-one (Donkeng Dazie, Liška, Ludvík, Fábry \& Dušek, 2016), green triangles refer to (VI) (Donkeng Dazie et al., 2017) and blue triangles refer to the title molecule, (V).

Table 1 lists the extremal deviations from the fitted planes through the core atoms of the pyrrole rings in the title structure, i.e. without the carbonyl O atoms, which were omitted from considerations. Fig. 4 illustrates the dependence of the maximal deviations from the best plane through the core atoms of the pyrrole rings on the $\mathrm{N}-\mathrm{C}_{\text {carbonyl }}$ distance. Compounds include the title structure, (V), the structures determined by Donkeng Dazie, Liška, Ludvík, Fábry \& Dušek (2016) and Donkeng Dazie et al. (2017), as well as 233 structures with the isoindolinone fragment (Table 1), which were retrieved from the Cambridge Structural Database (Version 5.36; Groom et al., 2016). (The retrieved structures contained no disorder and errors, while they were determined below 150 K , with $R$ factors $<0.05$; in case the structures contained two carbonyl groups, the retrieved data were collected twice

| $\mathrm{C} 11 \mathrm{~B}-\mathrm{H} 3 \mathrm{c} 11 B \cdots \mathrm{Cg} 2^{\text {iii }}$ | 0.98 | 2.95 | 173 | 3.9288 (14) |

Symmetry code: (iii): $x-\frac{1}{2},-y+\frac{1}{2}, z-\frac{1}{2}$.
and the variant with the larger $\mathrm{N}-\mathrm{C} 8$ distance was selected for further consideration.) Fig. 4 also shows that the largest distortion of the pyrrole ring takes place in (VI) (Donkeng Dazie et al., 2017), the distortion being milder in the title molecules and being mildest in 2-isopropyl-2,3-dihydro- 1 H -isoindol-1-one (Donkeng Dazie, Liška, Ludvík, Fábry \& Dušek, 2016). It indicates that the reasons for the distortion of the pyrrole rings from planarity are steric ones in these cases: tert-butyl as a more voluminous group causes a larger distortion in comparison with the isopropyl group. In (VI), an interaction between the bulky isoindolinone and isobenzofuran ring moieties also takes place.

## 4. Supramolecular features

The crystal packing of the molecules of (V) in the unit cell (Fig. 5) is relatively simple. There are two intermolecular C$\mathrm{H} \cdots \mathrm{O}$ interactions (Table 2), one linking the two independent

Figure 5
The packing of the title molecules in the unit cell. H atoms have been omitted for clarity. Colour key: C gray, N blue and O red.

Computer programs: CrysAlis PRO (Rigaku OD, 2015), SIR2014 (Burla et al., 2015), JANA2006 (Petříček et al., 2014), DIAMOND (Brandenburg \& Putz, 2005), Origin6. 1 (OriginLab, 2000) and PLATON (Spek, 2009).
molecules $\left(\mathrm{C} 4 B-\mathrm{H} \cdots \mathrm{O} 1 A^{\mathrm{ii}}\right)$ and the other linking only $A$ molecules $\left(\mathrm{C} 7 A-\mathrm{H} \cdots \mathrm{O} 1 A^{\mathrm{i}}\right)$. Weak $\mathrm{C}-\mathrm{H} \cdots \pi$-electron interactions involving only $B$ molecules (Table 3) are also present. No $\pi-\pi$-electron ring interactions are present in the structure.

## 5. Database survey

The survey relating particularly to the structural features of the isoindolinone ring system has been covered in $\S 3$.

## 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4. All H atoms were discernible in difference electron-density maps. However, the aryl, methylene and methyl H atoms were constrained, with aryl $\mathrm{C}-\mathrm{H}=$ $0.95 \AA$, methylene $\mathrm{C}-\mathrm{H}=0.99 \AA$ and methyl $\mathrm{C}-\mathrm{H}=0.98 \AA$,
and with $U_{\text {iso }}(\mathrm{H})=1.5 U_{\text {eq }}(\mathrm{C})$ for methyl H atoms and $1.2 U_{\text {eq }}(\mathrm{C})$ otherwise.

## Funding information

Funding for this research was provided by: Grantová Agentura České Republiky (grant No. 13-21704S), as well as by institutional support (RVO: 61388955). The equipment of the ASTRA laboratory, which was established within the Operation Program Prague Competitiveness (project CZ.2.16/3.1.00/ 24510), was used for the single-crystal diffraction experiment
