chandru@lamar.edu

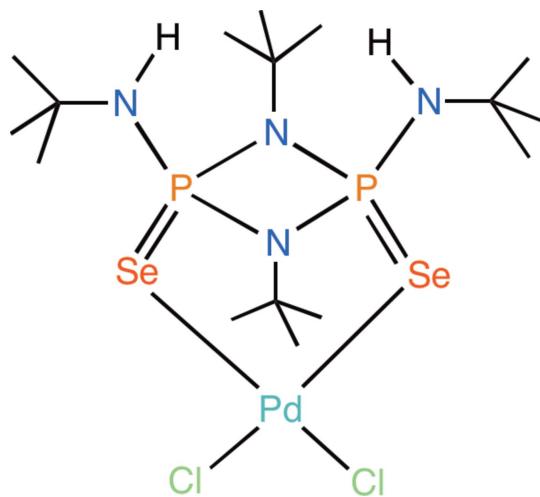

A palladium(II) complex {systematic name: dichlorido[1,3-di-*tert*-butyl-2,4-bis(*tert*-butylamino)-1,3,2 $\lambda^5$ ,4 $\lambda^5$ -diazadiphosphetidine-2,4-diselone- $\kappa^2\text{Se},\text{Se}'$ ]palladium(II)}, *cis*-[PdCl<sub>2</sub>]**I**], **II**, containing a bis(selenium) ligand based on cyclodiphosph(V)azane, *cis*-[ $(^t\text{BuNH})(\text{Se})\text{P}(\mu-\text{N}^t\text{Bu})_2\text{P}(\text{Se})(\text{NH}^t\text{Bu})$ ], **I**, has been synthesized and structurally characterized. The crystal structure of complex **II** reveals that the ligand chelates through selenium donors with the natural bite-angle of 110.54 (1) $^\circ$  and a Pd–Se bond distance of 2.444 (1) Å. The coordination around Pd<sup>II</sup> shows a slightly distorted square-planar geometry, as indicated by the angle between the [PdCl<sub>2</sub>] and [PdSe<sub>2</sub>] planes of 5.92 (3) $^\circ$ . In the crystal, the molecules are interlinked through weak N–H $\cdots$ Cl and C–H $\cdots$ Cl hydrogen-bonding interactions.

### 1. Chemical context

Cyclodiphosph(III)azanes are four-membered P<sup>III</sup>–N ring systems with general formula, *cis*-[RP( $\mu$ -N<sup>t</sup>Bu)<sub>2</sub>PR]. The planar nature of the four-membered ring favors a bridging bidentate coordination mode through phosphorus donors rather than chelation, to afford structurally interesting macrocyclic and polymeric complexes (Balakrishna, 2016). The main-group chemistry of the corresponding P<sup>V</sup> analogue cyclodiphosph(V)azanes, *cis*-[R(E)P( $\mu$ -N<sup>t</sup>Bu)<sub>2</sub>P(E)R] (E = O, S, Se, and Te; R = NH<sup>t</sup>Bu) and its amide derivatives has been studied extensively by Stahl (2000) and Briand and co-workers (Briand *et al.*, 2002). While examples of coordination of cyclodiphosph(V)azanes with transition metal ions are scarce, the sulfur and selenium derivatives are especially interesting as they have a special affinity for soft metals and have the potential to form complexes with wide natural bite-angles through chelation (Chivers *et al.*, 2001). Several late transition-metal complexes containing wide natural bite-angle chelating ligands ( $L$ –M–L = 100–134 $^\circ$ ) have been developed over the years and have shown promising catalytic activity for several reactions (Kamer *et al.*, 2001). The majority of these wide bite-angle ligands are phosphorus and/or nitrogen donor ligands (Motolko *et al.*, 2017; Czauderna *et al.*, 2015). Herein we report the synthesis and crystal structure of the palladium(II) complex **II** with a wide bite-angle selenium ligand based on cyclodiphosph(V)azane *cis*-[ $(^t\text{BuNH})(\text{Se})\text{P}(\mu-\text{N}^t\text{Bu})_2\text{P}(\text{Se})(\text{NH}^t\text{Bu})$ ], **I**.

OPEN ACCESS

## 2. Structural commentary

A perspective view of the molecular structure of the  $\text{Pd}^{\text{II}}$  complex (**II**) is presented in Fig. 1. The crystal structure of **II** confirms the chelation of *cis*-[ $(\text{'BuNH})(\text{Se})\text{P}(\mu\text{-N'}\text{Bu})_2\text{P}(\text{Se})(\text{NH'}\text{Bu})$ ] (**I**) through selenium donors to the  $[\text{PdCl}_2]$  moiety, with a  $\text{Se}_1\text{-Pd}_1\text{-Se}_2$  natural bite-angle of  $110.54(1)^\circ$ . The rigid four-membered cyclodiphosphazane  $[\text{P}(\mu\text{-N'}\text{Bu})_2\text{P}]$  ligand backbone enforces large natural bite-angles. The  $\text{Se}_1\text{-Pd}_1\text{-Cl}_1$  and  $\text{Se}_2\text{-Pd}_1\text{-Cl}_2$  bond angles are  $79.27(2)$  and  $79.36(2)^\circ$ , respectively, smaller than the natural square-planar angle, whereas the  $\text{Cl}_1\text{-Pd}_1\text{-Cl}_2$  angle [ $91.19(2)^\circ$ ] is closer to the typical value for a square-planar angle. In complex **II**, the exocyclic  $\text{Se}_1\text{-P}_1\text{-N}_3$  and  $\text{Se}_2\text{-P}_2\text{-N}_4$  angles at  $114.32(7)$  and  $117.13(7)^\circ$ , respectively, are slightly larger than

**Table 1**  
Hydrogen-bond geometry ( $\text{\AA}$ ,  $^\circ$ ).

$D\text{-H}\cdots A$	$D\text{-H}$	$H\cdots A$	$D\cdots A$	$D\text{-H}\cdots A$
$\text{N}_4\text{-H}_4\cdots \text{Cl}_1^{\text{i}}$	0.91	2.45	3.317 (2)	159
$\text{N}_3\text{-H}_3\cdots \text{Cl}_1^{\text{i}}$	0.91	2.57	3.4160 (19)	155
$\text{C}_{16}\text{-H}_{16A}\cdots \text{Cl}_2^{\text{ii}}$	0.98	2.82	3.746 (5)	157
$\text{C}_{14A}\text{-H}_{14E}\cdots \text{Cl}_2^{\text{ii}}$	0.98	2.82	3.742 (7)	157

Symmetry codes: (i)  $x - \frac{1}{2}, y, -z + \frac{1}{2}$ ; (ii)  $x - \frac{1}{2}, -y + \frac{1}{2}, -z + 1$ .

the corresponding angle in the uncoordinated ligand **I** [107.3 (1) and  $113.2(1)^\circ$ ; Chivers *et al.*, 2002]. In complex **II**, the palladium atom shows a slight tetrahedral distortion from a square-planar geometry, as indicated by the dihedral angle between the  $\text{Se}_1/\text{Pd}_1/\text{Se}_2$  and  $\text{Cl}_1/\text{Pd}_1/\text{Cl}_2$  planes of  $5.92(3)^\circ$ . The  $\text{Pd}_1\text{-Se}_1$  and  $\text{Pd}_1\text{-Se}_2$  bond distances are  $2.4458(3)$  and  $2.4440(3)$   $\text{\AA}$ , respectively, and are in the typical range for  $\text{Pd}^{\text{II}}$  complexes with selenium ligands (Das *et al.*, 2009). In complex **II**, the  $\text{P}_1\text{-Se}_1$  and  $\text{P}_2\text{-Se}_2$  bond distances are  $2.1543(6)$  and  $2.1654(6)$   $\text{\AA}$ , respectively; these bonds are slightly elongated compared to the  $\text{P}-\text{Se}$  bond [ $2.078(1)$   $\text{\AA}$ ] in the uncoordinated ligand (**I**). This may be a result of the coordination of Se to the Pd center. The  $\text{Pd}-\text{Cl}$  bond distances [ $\text{Pd}_1\text{-Cl}_1 = 2.3381(6)$  and  $\text{Pd}_1\text{-Cl}_2 = 2.3159(6)$   $\text{\AA}$ ] are consistent with those reported for  $\text{Pd}^{\text{II}}$  complexes with Se donor ligands (Saleem *et al.*, 2013). The  $[\text{P}(\mu\text{-N'}\text{Bu})_2\text{P}]$  ring in complex **II** is greatly puckered, as indicated by the angle of  $22.61(2)^\circ$  between the  $\text{N}_1/\text{P}_1/\text{N}_2$  and  $\text{N}_1/\text{P}_2/\text{N}_2$  planes. The corresponding dihedral angle for the uncoordinated ligand is  $3.73(2)^\circ$ .

## 3. Supramolecular features

In the crystal, the molecules are connected through weak  $\text{N}-\text{H}\cdots\text{Cl}$  and  $\text{C}-\text{H}\cdots\text{Cl}$  hydrogen-bonding interactions (Fig. 2, Table 1). Interestingly, in the solid-state structure **II**, the exocyclic nitrogen substituents are arranged in an *endo, endo* fashion, whereas in ligand **I** they are arranged in *exo, endo* orientations (Chivers *et al.*, 2002). An overlay plot of the free ligand molecule **I** with the ligand fragment of **II** is shown in Fig. 3. This conformational change upon coordination is possibly caused by the formation of intermolecular hydrogen-bonding interactions. A similar conformational change influenced by hydrogen-bonding interactions has previously been noted (Chandrasekaran *et al.*, 2011).

## 4. Synthesis and crystallization

The ligand *cis*-[ $(\text{'BuHN})(\text{Se})\text{P}(\mu\text{-N'}\text{Bu})_2\text{P}(\text{Se})(\text{NH'}\text{Bu})$ ], (**I**), was prepared following a reported procedure (Chivers *et al.*, 2002).

A dichloromethane solution (10 mL) of  $[\text{Pd}(\text{COD})\text{Cl}_2]$  (100 mg, 0.35 mmol) was added dropwise to a solution of *cis*-[ $(\text{'BuHN})(\text{Se})\text{P}(\mu\text{-N'}\text{Bu})_2\text{P}(\text{Se})(\text{NH'}\text{Bu})$ ] (175 mg, 0.35 mmol) in 10 mL of  $\text{CH}_2\text{Cl}_2$  under an  $\text{N}_2$  atmosphere at ambient temperature. The resultant dark-orange solution was stirred

Hydrogen-bonding interactions in the crystal lattice.

for 6 h. The solution was then concentrated to 10 mL, diluted with 10 mL of pentane, and stored at 248 K for a day to afford the analytically pure orange crystalline product. X-ray quality crystals were obtained by slow evaporation from a DMF solution at room temperature. Yield: 76% (206 mg, 0.067 mmol), m.p. 455–457 K.

## 5. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. All H atoms attached to carbon were placed in calculated positions (C—H = 0.98 Å), while those attached to nitrogen were placed in locations derived from a difference-Fourier map and their coordinates adjusted to give N—H = 0.91 Å. All were included as riding contributions with *U*<sub>iso</sub>(H) = 1.2–1.5 times those of the parent atoms. The *t*-butyl group attached to N4 was modeled as rotationally disordered over two sites of approximately equal population. These were refined with restraints so that the geometries of the two components of the disorder are comparable.

## Funding information

where  $P = (F_o^2 + 2F_c^2)/3$

$(\Delta/\sigma)_{\max} = 0.002$   
 $\Delta\rho_{\max} = 1.10 \text{ e } \text{\AA}^{-3}$

$\Delta\rho_{\min} = -0.82 \text{ e } \text{\AA}^{-3}$

### Special details

**Experimental.** The diffraction data were obtained from 3 sets of 400 frames, each of width  $0.5^\circ$  in  $\omega$ , collected at  $\varphi = 0.00, 90.00$  and  $180.00^\circ$  and 2 sets of 800 frames, each of width  $0.45^\circ$  in  $\varphi$ , collected at  $\omega = -30.00$  and  $210.00^\circ$ . The scan time was 10 sec/frame.

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted R-factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional R-factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > 2\text{sigma}(F^2)$  is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and R-factors based on ALL data will be even larger. H-atoms attached to carbon were placed in calculated positions ( $C-H = 0.98 \text{ \AA}$ ) while those attached to nitrogen were placed in locations derived from a difference map and their coordinates adjusted to give  $N-H = 0.91 \text{ \AA}$ . All were included as riding contributions with isotropic displacement parameters 1.2 - 1.5 times those of the attached atoms. The *t*-butyl group attached to N4 is rotationally disordered over two sites of approximately equal population. These were refined with restraints that the geometries of the two components of the disorder be comparable.
