# Crystal structure of bis\{ $\mu$-2-methoxy-6-[(methyl-imino)methyl]phenolato\}bis(\{2-methoxy-6[(methylimino)methyl]phenolato\}nickel(II)) involving different coordination modes of the same Schiff base ligand 

Olga Yu. Vassilyeva, ${ }^{\text {a* }}$ Vladimir N. Kokozay ${ }^{\text {a }}$ and Brian W. Skelton ${ }^{\text {b }}$

${ }^{\text {a}}$ Department of Chemistry, Taras Shevchenko National University of Kyiv, 64/13 Volodymyrska Street, Kyiv 01601, Ukraine, and ${ }^{\mathbf{b}}$ School of Molecular Sciences, M310, University of Western Australia, Perth, WA 6009, Australia. *Correspondence e-mail: vassilyeva@univ.kiev.ua

The structure of the title compound, $\left[\mathrm{Ni}_{2}\left(\mathrm{C}_{9} \mathrm{H}_{10} \mathrm{NO}_{2}\right)_{4}\right]$, is built up by discrete centrosymmetric dimers. Two nitrogen and three oxygen atoms of two Schiff base ligands singly deprotonated at the phenolate site form a square-pyramidal environment for each metal atom. The ligands are bonded differently to the metal centre: one of the phenolic O atoms is bound to one nickel atom, whereas another bridges the two metal atoms to form the dimer. The $\mathrm{Ni}-\mathrm{N} / \mathrm{O}$ distances fall in the range 1.8965 (13) -1.9926 (15) $\AA$, with the $\mathrm{Ni}-\mathrm{N}$ bonds being slightly longer; the fifth contact of the metal to the bridging phenolate oxygen atom is substantially elongated $[2.533$ (1) $\AA$ ]. A similar coordination geometry was observed in the isomorphous Cu analogue previously reported by us [Sydoruk et al. (2013). Acta Cryst. E69, m551-m552]. In the crystal, the $\left[\mathrm{Ni}_{2} L_{4}\right]$ molecules form sheets parallel to the $a b$ plane with the polar methoxy groups protruding into the intersheet space and keeping the sheets apart. Within a sheet, the molecules are stacked relative to each other in such a way that the $\mathrm{Ni}_{2} \mathrm{O}_{2}$ planes of neighbouring molecules are orthogonal.

## 1. Chemical context

The title compound, $\left[\mathrm{Ni}_{2}\left(\mathrm{C}_{9} \mathrm{H}_{10} \mathrm{NO}_{2}\right)_{4}\right]$, $\mathbf{1}$, has been synthesized as part of our long-term research on Schiff base metal complexes aimed at the preparation of mono- and heterometallic compounds of various compositions and structures, and the investigation of their potential applications. In these studies, we use direct synthesis of coordination compounds based on a spontaneous self-assembly in solution, in which the metal (or one of the metals in the case of heterometallic complexes) is introduced as a fine powder (zerovalent state) and oxidized by aerial dioxygen during the synthesis (Buvaylo et al., 2005, 2012; Kokozay et al., 2018).

The multidentate ligand 2-methoxy-6-[(methylimino)methyl]phenol, $\mathrm{H} L$, derived from 2-hydroxy-3-methoxy-benzaldehyde ( $o$-vanillin) and methylamine shows various connectivity fashions and can generate mono- and polymetallic complexes. The methoxy group plays an essential role in the coordination abilities of the Schiff base (Andruh, 2015). The singly deprotonated $\mathrm{H} L$ ligand has been shown to act as a multidentate linker between seven metal centres affording $\left[M_{7}\right]$ assemblies, where $M$ is a divalent $\mathrm{Ni}, \mathrm{Zn}$, Co or Mn ion (Meally et al., 2010, 2012; Zhang et al., 2010). The octahedral metal atoms in the heptanuclear cores are additionally supported by $\mu_{3}$-bridging $\mathrm{OH}^{-}$or $\mathrm{MeO}^{-}$groups that link the central metal atom to the
six peripheral ones. Of heterometallic examples with $\mathrm{H} L$, only four $1 s-3 d$ structures of $\mathrm{Na} / M(M=\mathrm{Fe}, \mathrm{Ni})$ complexes have been reported (Meally et al., 2013).

Our research efforts in the field have yielded novel heterometallic dinuclear $\mathrm{Co}^{\mathrm{III}} / \mathrm{Cd}$ and $\mathrm{Co}^{\mathrm{II}} / \mathrm{Zn}$ complexes bearing HL along with the 'parent' mononuclear complex $\mathrm{Co} L_{3} \cdot$ DMF ( $\mathrm{DMF}=N, N$-dimethylformamide; Nesterova et al., 2018, 2019; Vassilyeva et al., 2018). Their catalytic activity in stereospecific alkanes oxidation with $m$-chloroperbenzoic acid as an oxidant has been studied in detail. A comparison of the catalytic behaviours of the hetero- and monometallic analogues provided further insight into the origin of stereoselectivity of the oxidation of $\mathrm{C}-\mathrm{H}$ bonds. In the syntheses, the condensation reaction between $o$-vanillin and $\mathrm{CH}_{3} \mathrm{NH}_{2} \cdot \mathrm{HCl}$ was utilized without isolation of the resulting Schiff base. In the present work, the title compound was isolated in an attempt to prepare a heterometallic $\mathrm{Ni} / \mathrm{Sn}$ complex with $\mathrm{H} L$ in the reaction of nickel powder and $\mathrm{SnCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, with the Schiff base formed in situ in a methanol/ DMF mixture in a 1:1:2 molar ratio. Similarly to the synthesis of $\mathrm{Co} L_{3} \cdot$ DMF (Nesterova et al., 2018), $\mathrm{H} L$ does not enable the formation of a heterometallic Sn-containing species, in contrast to its compartmental analogues $3-R$-salicylaldehyde-

ethylenediamine ( $R=$ methoxy-, ethoxy-), $\mathrm{H} L^{\prime}$, that afford heterometallic, diphenoxido-bridged, dinuclear $\mathrm{Cu}^{\mathrm{II}} \mathrm{Sn}^{\mathrm{II}}$ cations $\left[\mathrm{Cu} L^{\prime} \mathrm{SnCl}\right]^{+}$(Hazra et al., 2016).

## 2. Structural commentary

The molecular structure of $\mathbf{1}$ exists as a centrosymmetric dimer [ $\mathrm{Ni}_{2} L_{4}$ ] (Fig. 1). The nickel atom is five-coordinate with two nitrogen and three oxygen atoms of two, singly deprotonated at the phenolate site Schiff base ligands. The ligands are bonded differently to the metal atoms: the phenolic oxygen atom O 21 is bound to one nickel atom, whereas O 11 bridges the two metal centres and forms the dimer.

The $\mathrm{Ni}-\mathrm{N}$ bonds are somewhat longer than the shortest $\mathrm{Ni}-\mathrm{O}$ distances (Table 1) while the fifth contact of the metal to the bridging oxygen atom is substantially elongated. The cis angles at the nickel atom are in the range 87.57 (6)-91.09 (6) ${ }^{\circ}$, with the two trans angles being 170.92 (6) and 175.66 (6) ${ }^{\circ}$ (Table 1). The angular structural index parameter, $\tau=(\beta-\alpha) /$ 60 , evaluated from the two largest angles $(\alpha<\beta)$ in the fivecoordinate geometry is 0.08 compared with ideal values of 1 for an equilateral bipyramid and 0 for a square pyramid. Hence, the nickel coordination polyhedron in $\mathbf{1}$ is a square pyramid with minimal distortion. The apical position of the coordination sphere is occupied by the bridging phenolate oxygen $\mathrm{O} 11(1-x, 1-y, 1-z)$ with a bridging angle of 101.44 (2) ${ }^{\circ}$.

We reported a similar coordination geometry for the isomorphous Cu analogue [ $\mathrm{Cu}_{2} L_{4}$; Sydoruk et al., 2013]. The main difference between the two structures is the proximity of the metal centres in the dimers, which are further apart in the Ni complex compared to the Cu compound. The $\mathrm{Ni} \cdot \cdots \mathrm{Ni}$ distance is $3.4638(4)$ compared to the $\mathrm{Cu} \cdots \mathrm{Cu}$ separation of 3.3737 (2) $\AA$. In addition, the $\mathrm{Cu}-\mathrm{O} 11(1-x, 1-y, 1-z)$ contact in $\left[\mathrm{Cu}_{2} L_{4}\right]$ is shorter [2.4329 (7) $\AA$ A .

## 3. Supramolecular features

There are no significant intermolecular interactions between the dimers in the crystal lattice. Classical hydrogen-bonding interactions are absent in $\mathbf{1}$. The molecules form sheets parallel to the $a b$ plane with the non-coordinating polar methoxy groups protruding into the intersheet space and keeping the sheets apart (Fig. 2). Within a sheet, the molecules pack relative to each other in such a way that neighbouring $\mathrm{Ni}_{2} \mathrm{O}_{2}$ planes are orthogonal (Fig. 3). The minimum $\mathrm{Ni} \cdots \mathrm{Ni}$

Figure 2
Crystal packing of $\mathbf{1}$ showing sheets of $\left[\mathrm{Ni}_{2} L_{4}\right]$ molecules parallel to the $a b$ plane. H atoms are not shown.
separations inside a sheet and between adjacent sheets are about 7.099 and $11.374 \AA$, respectively. The $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interaction between $\mathrm{C} 28-\mathrm{H} 28 A$ and $\mathrm{O} 22\left(x+\frac{1}{2},-y+\frac{3}{2},-z+1\right)$ $[\mathrm{C} 28-\mathrm{H} 28 A=0.98 \AA, \mathrm{H} 28 A \cdots \mathrm{O} 22=2.57 \AA, \mathrm{C} 28 \cdots \mathrm{O} 22=$ 3.449 (2) $\AA$ and $\mathrm{C} 28-\mathrm{H} 28 A \cdots \mathrm{O} 22=150^{\circ}$ ] is very weak.

## 4. Database survey

A search in the Cambridge Structural Database (CSD; Groom et al., 2016) for $\mathrm{H} L$ and its complexes via the WebCSD interface in March 2019 reveals that 39 original crystal structures, including the structure of the ligand itself, have been reported. Polynuclear complexes constitute the majority of the structures with 17 examples of $\left[M^{\mathrm{II}}{ }_{7}\right](M=\mathrm{Mn}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Zn})$ assemblies featuring planar hexagonal disc-like cores and three examples of dimeric $\left(\mathrm{Cu}_{2}\right)$ and tetrameric complexes with the cubane- $\left(\mathrm{Mn}_{4}\right)$ or open-cubane type cores $\left(\mathrm{Co}_{4}\right)$. The singly deprotonated $H L$ ligand evidently encourages the formation of polynuclear metal complexes only with assistance from other bridging ligands. The integrity of the hepta[ $M^{\mathrm{II}}{ }_{7} L_{6}$ ] and tetranuclear $\left[\mathrm{Mn}_{4} L_{3}\right],\left[\mathrm{Co}_{4} L_{2}\right]$ polymetallics is secured by $\mu_{3}$-bridging $\mathrm{OH}^{-} / \mathrm{MeO}^{-}$groups and other ligands, respectively. A higher metal-to-ligand ratio (1:2 and 1:3) in the absence of bridging ligands stimulates the formation of mononuclear complexes, as evidenced by the 10 structures with molecular ( Mn , Co and Pt ) or polymeric $(\mathrm{Mn})$ arrangements in the crystal lattice. The four heterometallic examples
with $\mathrm{H} L$ published by others are limited to $\mathrm{Na} / M(M=\mathrm{Fe}, \mathrm{Ni})$ complexes whose formation was induced by the use of sodium salts and/or NaOH in the synthesis. The $3 d-3 d / 4 d$ heterometallics recently reported by our group are based on the neutral $\mathrm{Co}^{\text {III }} L_{3}$ species with the metal centre in a mer configuration that acts as a metalloligand to $\mathrm{Zn}^{2+} / \mathrm{Cd}^{2+}$ ions, generating $\left[\mathrm{CoML} L_{3} \mathrm{Cl}_{2}\right]$ •Solv $\left(\right.$ Solv $\left.=\mathrm{H}_{2} \mathrm{O}, \quad \mathrm{CH}_{3} \mathrm{OH}\right)$ complexes.

## 5. Synthesis and crystallization

$o$-Vanillin $(0.3 \mathrm{~g}, 2.0 \mathrm{mmol})$ in 10 mL of methanol was stirred with $\mathrm{CH}_{3} \mathrm{NH}_{2} \cdot \mathrm{HCl}(0.14 \mathrm{~g}, 2.0 \mathrm{mmol})$ in the presence of dimethylaminoethanol $(0.1 \mathrm{~mL})$ in a 50 mL conical flask at 333 K for half an hour. $\mathrm{SnCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(0.23 \mathrm{~g}, 1.0 \mathrm{mmol})$ dissolved in 10 mL of DMF and Ni powder $(0.06 \mathrm{~g}, 1.0 \mathrm{mmol})$ were added to the resulting yellow solution of the preformed Schiff base. The mixture gradually turned brown while it was magnetically stirred at 333 K to achieve dissolution of the nickel ( 2 h ; adhesion of a small fraction of the metal particles to the stirring bar precluded complete dissolution of the metal

Figure 3

Figure 4
IR spectrum of $\mathbf{1}$ in a KBr pellet.
powder). The resultant brown solution was filtered and left to stand at room temperature. Dark-brown, almost black, prisms of $\mathbf{1}$ formed in two weeks. They were filtered off, washed with dry $\mathrm{Pr}^{\mathrm{i}} \mathrm{OH}$ and dried in air. Yield (based on Ni ): $31 \%$. Analysis calculated for $\mathrm{C}_{36} \mathrm{H}_{40} \mathrm{~N}_{4} \mathrm{Ni}_{2} \mathrm{O}_{8}$ (774.14): C 55.86, H 5.21, N $7.24 \%$. Found: C 55.62, H 5.33, N 7.11\%.

A broad band centered at about $3440 \mathrm{~cm}^{-1}$ in the IR spectrum of $\mathbf{1}$ may be due to adsorbed water molecules (Fig. 4). Several bands arising above and below $3000 \mathrm{~cm}^{-1}$ are assigned to aromatic $=\mathrm{CH}$ and alkyl -CH stretching, respectively. The characteristic $\nu(\mathrm{C}=\mathrm{N})$ absorption of the Schiff base which appears at $1634 \mathrm{~cm}^{-1}$ as a strong intense band in the IR spectrum of HL (Nesterova et al., 2018) is detected at $1630 \mathrm{~cm}^{-1}$ in the spectrum of 1. A number of sharp and intense bands are observed in the aromatic ring stretching ( $1600-1400 \mathrm{~cm}^{-1}$ ) and $\mathrm{C}-\mathrm{H}$ out-of-plane bending regions ( $800-700 \mathrm{~cm}^{-1}$ ).

## 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. Hydrogen atoms were placed at idealized positions and refined using a riding model: $\mathrm{C}-\mathrm{H}=$ $0.95 \AA$ with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$ for $\mathrm{CH}, 0.98 \AA$ and $1.5 U_{\text {eq }}(\mathrm{C})$ for $\mathrm{CH}_{3}$.

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. Three low theta reflections, considered to be partly hidden by the beam stop were omitted from the refnement.
