Three huntite-type aluminoborates of stoichiometry $R E \mathrm{Al}_{3}\left(\mathrm{BO}_{3}\right)_{4}(R E=\mathrm{Tb}$, Dy and Ho), namely, terbium/dysprosium/holmium trialuminium tetrakis(borate), were synthesized by slow cooling within a $\mathrm{K}_{2} \mathrm{Mo}_{3} \mathrm{O}_{10}$ flux with spontaneous crystallization. The crystal structures were determined using single-crystal X-ray diffraction (SC-XRD) data. The synthesized borates are isostructural to the huntite $\left[\mathrm{CaMg}_{3}\left(\mathrm{CO}_{3}\right)_{4}\right]$ structure and crystallized within the trigonal $R 32$ space group. The structural parameters were compared to literature data of other huntite $R E \mathrm{Al}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ crystals within the $R 32$ space group. All three borates fit well into the trends calculated from the literature data. The unit-cell parameters and volumes increase linearly with larger $R E$ cations whereas the densities decrease. All of the crystals studied were refined as inversion twins.

## 1. Chemical context

Rare-earth aluminum borates (REAB) with the general chemical formula $R E \mathrm{Al}_{3}\left(\mathrm{BO}_{3}\right)_{4}(R E=\mathrm{La}, \mathrm{Pr}, \mathrm{Nd}, \mathrm{Sm}, \mathrm{Eu}, \mathrm{Gd}$, $\mathrm{Tb}, \mathrm{Dy}, \mathrm{Ho}, \mathrm{Er}, \mathrm{Tm}, \mathrm{Yb}, \mathrm{Lu}, \mathrm{Y}$ ) have been studied extensively for applications in lasers, nonlinear optics, sensors, and phosphors because of their optical and magnetoelectric properties as well as the capacity to be doped with other rare-earth metals (Koporulina et al., 2000; Leonyuk \& Leonyuk, 1995; Leonyuk et al., 1998; Mills, 1962; Belokoneva \& Timchenko, 1983; Belokoneva, 1994). The REAB crystals are promising materials for self-frequency-doubling lasers as their nonlinear optical properties can be changed by doping with different rare-earth elements including $\mathrm{Nd}, \mathrm{Dy}, \mathrm{Er}, \mathrm{Yb}, \mathrm{Tm}$, or Y (Leonyuk et al., 1998, 2007; Földvári et al., 2003; Chen et al., 2012). The REAB compounds with $R E=\mathrm{Tb}, \mathrm{Ho}, \mathrm{Er}$, or Tm exhibit the magnetoelectric properties useful for sensor applications (Liang et al., 2011, 2012), and REAB with the $R E$ $=\mathrm{Pr}, \mathrm{Sm}, \mathrm{Eu}, \mathrm{Gd}, \mathrm{Tb}$, or Ho can be used as phosphors (Li \& Wang, 2007; He et al., 2015).

The REAB compounds are generally synthesized by a fluxassisted growth method with or without seeds at $800-1150^{\circ} \mathrm{C}$ (Leonyuk \& Leonyuk, 1995; Koporulina et al., 2000; Wang, 2012; Leonyuk, 2017). The $\mathrm{K}_{2} \mathrm{Mo}_{3} \mathrm{O}_{10}$ (Tu et al., 1994; Wang et al., 1995; Leonyuk \& Leonyuk, 1995; Teshima et al., 2006) compound is the most commonly used flux for the crystallization of REAB, although other fluxes such as $\mathrm{Bi}_{2} \mathrm{O}_{3}-\mathrm{B}_{2} \mathrm{O}_{3}$ (Chani et al., 1994) and $\mathrm{BaO}-\mathrm{B}_{2} \mathrm{O}_{3}$ (Jung et al., 1995) have been used. Two major drawbacks of using the $\mathrm{K}_{2} \mathrm{Mo}_{3} \mathrm{O}_{10}$ flux are the potential incorporation of Mo into the REAB structure and co-crystallization of other phases (Wang, 2012;

Leonyuk, 2017; Kuz'micheva et al., 2019). In the current study, $\mathrm{K}_{2} \mathrm{Mo}_{3} \mathrm{O}_{10}$ flux was used to synthesize $R E \mathrm{Al}_{3}\left(\mathrm{BO}_{3}\right)_{4}(R E=\mathrm{Tb}$, Dy , Ho) crystals, and the structural parameters of the synthesized REAB crystals were compared to literature data.

## 2. Structural commentary

The crystal structures of the synthesized REAB crystals are isostructural to the huntite structure (Mills, 1962) with the R32 space group (Fig. 1). The huntite aluminoborates generally crystallize within the $R 32$ space group; however, REAB compounds with $R E=\mathrm{Pr}, \mathrm{Nd}, \mathrm{Sm}, \mathrm{Eu}, \mathrm{Tb}, \mathrm{Ho}$, or Gd showed the transition in space group from $R 32$ to lower symmetry monoclinic $C 2 / c$ and $C 2$ space groups in the disordered structures caused by variations in the growth temperature, cooling rate, and composition (Belokoneva \& Timchenko, 1983; Belokoneva et al., 1988, 1994; Leonyuk \& Leonyuk, 1995; Plachinda \& Belokoneva, 2008; Leonyuk, 2017). The structures of the REAB crystals are composed of rare-earth cations with a distorted trigonal-prismatic coordination $\left(\mathrm{REO}_{6}\right)$, aluminum cations with a distorted octahedral coordination $\left(\mathrm{AlO}_{6}\right)$, and boron cations with a trigonal-planar coordination $\left(\mathrm{BO}_{3}\right)$ as shown in Fig. 2. The $\mathrm{AlO}_{6}$ octahedra form helical chains along the $c$-axis direction by sharing edges, and these chains are connected by $\mathrm{BO}_{3}$ units (see Fig. 3).

The structural parameters of the synthesized REAB compounds were added to literature data for comparison (see Fig. 4), and they were in good agreement when plotted versus the average ionic crystal radius of the six-coordinated RE element according to Shannon (1976). The trendlines show that the unit-cell parameters and volumes increase linearly whereas the densities decrease with the larger rare-earth cations in the structures. The data included in Fig. 4 include literature data for $R E \mathrm{Al}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ where $R E=\mathrm{Pr}, \mathrm{Nd}, \mathrm{Sm}, \mathrm{Eu}$, $\mathrm{Gd}, \mathrm{Tb}, \mathrm{Dy}, \mathrm{Ho}, \mathrm{Er}, \mathrm{Tm}, \mathrm{Yb}$, or Lu , as well as mixtures of $\mathrm{Y} / \mathrm{Er}$ and Y/Nd (Belokoneva et al., 1981; Hong \& Dwight, 1974; Xu et al., 2002; Jia et al., 2006; Kuroda et al., 1981; Leonyuk \& Leonyuk, 1995; Malakhovskii et al., 2014; Mészáros et al., 2000; Mills, 1962; Plachinda \& Belokoneva, 2008; Prokhorov et al., 2013, 2014; Sváb et al., 2012; Wang et al., 1991).

## 3. Synthesis and crystallization

The REAB single crystals were synthesized using $\mathrm{Tb}_{2} \mathrm{O}_{3}$ (Alfa Aesar, 99.9\%), $\mathrm{Dy}_{2} \mathrm{O}_{3}$ (Alfa Aesar, 99.9\%), $\mathrm{Ho}_{2} \mathrm{O}_{3}$ (Alfa Aesar, $99.9 \%$ ), $\mathrm{Al}(\mathrm{OH})_{3}$ (Almatis, $99.5 \%$ ), $\mathrm{B}_{2} \mathrm{O}_{3}$ (Alfa Aesar, $99.98 \%$ ), and $\mathrm{K}_{2} \mathrm{Mo}_{3} \mathrm{O}_{10}$ flux. All the rare-earth oxides, $\mathrm{Al}(\mathrm{OH})_{3}$, and $\mathrm{B}_{2} \mathrm{O}_{3}$ were used as received; the $\mathrm{B}_{2} \mathrm{O}_{3}$ was stored and handled in a nitrogen glovebox to prevent hydration (M-Braun, Inc., $<0.1 \mathrm{ppm}$ of $\mathrm{O}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$ ). The $\mathrm{K}_{2} \mathrm{Mo}_{3} \mathrm{O}_{10}$ flux was synthesized using $\mathrm{K}_{2} \mathrm{CO}_{3}$ (Alfa Aesar, $99 \%$ ) and $\mathrm{MoO}_{3}$ (Alfa Aesar, $99.5 \%$ ). For the flux, appropriate amounts of $\mathrm{K}_{2} \mathrm{CO}_{3}$ and $\mathrm{MoO}_{3}$ were mixed in a mortar and pestle and placed into a $\mathrm{Pt} / 10 \% \mathrm{Rh}$ crucible. The crucible was heated to $520^{\circ} \mathrm{C}$ at $5^{\circ} \mathrm{C} \mathrm{min}{ }^{-1}$, maintained at that temperature for 8 h , and then cooled down to room temperature at $5^{\circ} \mathrm{C} \mathrm{min}^{-1}$. For the synthesis of the REAB crystals, the rare-earth oxide was mixed with $\mathrm{Al}(\mathrm{OH})_{3}$ and $\mathrm{B}_{2} \mathrm{O}_{3}$ in a 1:6:5 molar ratio, and then $\mathrm{K}_{2} \mathrm{Mo}_{3} \mathrm{O}_{10}$ was added at 40 mass \% of the total precursor mass. The mixed powder of each rare-earth element was put into a $\mathrm{Pt} / 10 \% \mathrm{Rh}$ crucible, tightly covered with a $\mathrm{Pt} / 10 \% \mathrm{Rh}$ lid, and placed in a Thermolyne box furnace. The furnace was heated to $900^{\circ} \mathrm{C}$ at $5^{\circ} \mathrm{C}$

Figure 3
Structure showing the helical chains composed of edge sharing $\mathrm{AlO}_{6}$ units along the $c$ axis connected by $\mathrm{BO}_{3}$ in $R E \mathrm{Al}_{3}\left(\mathrm{BO}_{3}\right)_{4}$.

Figure 4
Summary of (a) unit-cell parameter $a,(b)$ unit-cell parameter $c,(c)$ unit-cell volume $(V)$, and $(d)$ density $(\rho)$ as a function of the average ionic crystal radii of the $R E$ in the crystal structures (coordination number $=6$ ) from Shannon (1976).

Figure 5
Back-scattered electron SEM micrographs of $R E \mathrm{Al}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ crystals including (a) and $(b) \mathrm{SmAl}_{3}\left(\mathrm{BO}_{3}\right)_{4},(c) \mathrm{TbAl}_{3}\left(\mathrm{BO}_{3}\right)_{4}$, (d) $\mathrm{DyAl}_{3}\left(\mathrm{BO}_{3}\right)_{4}$, (e) $\mathrm{HoAl}_{3}\left(\mathrm{BO}_{3}\right)_{4}$, and $(f) \mathrm{LuAl}_{3}\left(\mathrm{BO}_{3}\right)_{4}$. Note that some $\mathrm{KLu}\left(\mathrm{MoO}_{4}\right)_{2}$ crystals are seen in $(a)$ and $(d)$ as the smaller and brighter crystallites.
$\min ^{-1}$, maintained at that temperature for 4 h , cooled to $400^{\circ} \mathrm{C}$ at $5^{\circ} \mathrm{Ch}^{-1}$, and then shut off to cool naturally. The synthesized products were washed with deionized water in a sonic bath, and the crystals were recovered with vacuum filtration using a Büchner funnel. The REAB crystals along with $\operatorname{KRE}\left(\mathrm{MoO}_{4}\right)_{2}$ were synthesized by this process as expected from previous studies (Leonyuk et al., 1998; Teshima et al., 2006; Leonyuk, 2017; Kuz'micheva et al., 2019).

The REAB crystals generally have hexagonal prismatic shapes, and they were often agglomerated (Fig. 5), as observed with scanning electron microscopy (JSM-7001F field emission gun SEM; JEOL USA, Inc.). Crystals of $\mathrm{SmAl}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ and $\mathrm{LuAl}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ were also grown using the same procedure as described above and these are shown in Fig. 5 for comparison; however, the crystal structures are not reported due to the poor diffraction of $\mathrm{SmAl}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ and unresolvable displacement parameters during structural refinement for $\mathrm{LuAl}_{3}\left(\mathrm{BO}_{3}\right)_{4}$. Finally, for the crystal growth conditions used here, the average crystallite sizes for the different $\mathrm{REAl}_{3}\left(\mathrm{BO}_{3}\right)_{4}$ crystals herein $(R E=\mathrm{Sm}, \mathrm{Tb}, \mathrm{Dy}, \mathrm{Ho}, \mathrm{Lu})$ are shown in Fig. 6 with standard deviations based on measurements of $\geq 7$ crystals from each sample.

## 4. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. Suitable crystals were selected for SC-XRD and were placed on cryoloops in oil (Parabar 10312,
