09.4-15 ORGANOCOBALT COMPLEXES WITH A BUCKLED EQUATORIAL LIGAND. By V. B. Pett, R. W. Jones, A. M. Mulichak, P. L. Choo, J. W. Bacon, D. E. Zacharias, J. P. Glusker, Department of Chemistry, The College of Wooster, Wooster, Ohio 44691.

New cobalt complexes I and II have been synthesized, where $\mathrm{R}=$ methyl, ethyl, 2-methylpropyl, and $\mathrm{L}=\mathrm{OH}_{2}$, imidazole. These complexes, in which the equatorial ligand is distorted due to a seven-membered chelate ring, may serve as models for $\mathrm{B}_{12}$ coenzyme, since the equatorial corrin ring in that compound is ruffled.

Synthesis of the equatorial ligand was adapted from literature reports (Martin, J.W.L. et al. Inorg. Chem. (1981) 20 , 814). I is prepared by mixing the equatorial ligand with $\mathrm{CoCl}_{2}$ in acetone under argon, followed by exposure to air. II is obtained as the $\mathrm{ClO}_{4}$ salt by alkylation or I with RI in the presence of $\mathrm{NaBH}_{4}$ and water or imidazole, followed by recrystallization from $\mathrm{HClO}_{4}$. Elemental analyses, as well as ${ }^{2} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra are consistent with the structures shown.

I crystallizes in space group $P 2_{1} 2_{1} 2_{1}$, $a=14.017(2), b$ $=29.014(4), c=8.005(2) \AA, Z=8$. Anisotropic refinement of 2915 data gave $R=0.06, R_{W}=0.08$. The "fold angle" between the two halves of the ligand is $4^{\circ}$ and $12^{\circ}$ in the two molecules, which is as much as that observed in other complexes with considerably more steric demand from axial ligands (Parker, W.O., Jr. et al. Inorg. Chem. (1985) 24, 3908).

Likewise, the first structure of an organocobalt complex II ( $\mathrm{F}=$ ethyl, $\mathrm{L}=\mathrm{OH}_{2}$ ) in this series shows that the equatorial ligand is appreciably buckled (fold angle $-7^{\circ}$ ) ; [c2/c, $a=21.565(5), b=7.330(3), c=$ 25.172(6) $\AA, \beta=100.97(2), Z=8$, 2229 data; relatively high residuals, $R=0.10, R_{W}=0.13$, were due to disordered $\mathrm{ClO}_{4}{ }^{-}$.] The $\mathrm{Co}-\mathrm{C}$ bond length is somewhat longer ( $2.010(8) \AA$ ) than similar
dimethylglyoxime and "Costa" $\mathrm{B}_{12}$ models (Marzilli, L. G. et al. Inorg. Chim. Acta (1985) 107, 139), probably due to the additional steric demand of the equatorial ligand.

09.4-16 CRYSTAL STRUCTURES OF SDME COMPLEXES OF LANTHANIDES AND AMJND ACJDS. By Zheng Yifon, and Pan Kezhan. Fujian Institute of Research on the Structure of Matter, Academia Sinica, Fuzhou, China.

Some complexes were prepared from on aqueaus solution or $50 \%$ dioxane solution containing praseadymium perchloride and $\alpha$-amino acids. Intensity data have been collected on a CAD-4 diffractometer.
Thare are two types of crystal structure ( Type 1 and Type 2). In type 1, a pair of adjacent metal ions are briged by four carboxylate groups, while the type 2 has an infinjte threedimensional network with carboxyl briging group. In these two types of structure, the amino group in amino ocids is not coordinated to $\mathrm{Ln}^{3}$, and the carboxyl groups in amino ocids ore dissociated ond act as the bidentate bridging ligands, of which two oxygen atoms are coordinoted to different metal ions. The metal ions are seporoted from each other by a distance of more than $4 \dot{\lambda}$, so that there are no metal-metal bond between them. There are two types of structure in Glycine, but only first structure type in Mathionina. For different $\mathrm{Ln}^{3+}$ ion, however, there ore different structures in Serine. They suggest that steric effect play a predominant role in ditermining structures of the complexes of $\mathrm{Ln}^{3+}$ and amino ocids.
