## Keywords: Cobalt(III) complexes; Girar-T hydrazone; Crystal structure

Dark red monocrystals of title complex were prepared by the reaction of water solutions of $\mathrm{Na}_{3}\left[\mathrm{Co}\left(\mathrm{NO}_{2}\right)_{6}\right]$ and $\mathrm{L} \times 2 \mathrm{H}_{2} \mathrm{O}$ in mole ratio 1:1. The $\mathrm{Co}(\mathrm{III})$ is sited in an octahedral environment. The equatorial plane is formed by a tridentate coordination of the ligand (L) and one $\mathrm{NO}_{2}$ molecule, while the other two $\mathrm{NO}_{2}$ molecules are in axial positions. The ligand is coordinated to the $\mathrm{Co}(\mathrm{III})$ atom through $\mathrm{O} 3, \mathrm{~N} 1$ and O 4 atoms, forming two fused chelate rings, one being five-membered and one a six-membered one. All atoms in the chelate and phenyl rings are approximately coplanar. The angle between the mean plan of the equatorial $\mathrm{NO}_{2}$ and the mean plane defined by the two chelate rings is $28.1(3)^{\circ}$. The Co-N bond lengths for the two axial $\mathrm{NO}_{2}$ are about $0.03 \AA$ longer than that with the equatorial $\mathrm{NO}_{2}$. The two axial $\mathrm{NO}_{2}$ are coplanar. The complex molecule possesses eight oxygen atoms capable of acting as proton acceptors in the hydrogen bonds, but there are only two groups (one $\mathrm{N}-\mathrm{H}$ and one $\mathrm{O}-\mathrm{H}$ ) able to participate as proton donors. As a consequence, six oxygen atoms from $\mathrm{NO}_{2}$ ligands form weak C-H...O hydrogen bonds with only one exception for O 4 atom which participates in two strong $\mathrm{O}-\mathrm{H} . . . \mathrm{O}$ hydrogen bonds. Because of that the N-O4 bond is significantly longer than the rest of $\mathrm{N}-\mathrm{O}$ bonds in the $\mathrm{NO}_{2}$ ligands.

Data were collected on an Enraf-Nonius CAD-4 diffractometer using Mo $\mathrm{K} \alpha$ radiation ( $\lambda=0.71069 \AA$ ) and $\omega / 2 \theta$ scans in 1.41 to $25.47^{\circ} \theta$ range and were corrected for Lorentz and polarization effects. The structure was solved by direct methods and difference-Fourier methods, and refined by full matrix least-squares using SHELXL97 program to a final $\mathrm{R}=$ 0.0431 for 2938 reflections with I $>2 \sigma_{\mathrm{I}}$. Crystallographic data: $\mathrm{CoC}_{13} \mathrm{H}_{22} \mathrm{~N}_{7} \mathrm{O}_{10}, \mathrm{Mr}=495.3$, monoclinic, space group $\mathrm{P} 21 / \mathrm{c}$, a $=14.936(3) \AA, b=7.773(3) \AA, c=17.463(3) \AA, \beta=104.26(3)^{\circ}$, $\mathrm{V}=1964.9(9) \AA^{3}, \mathrm{Z}=4, \mathrm{D}_{\mathrm{c}}=1.674 \mathrm{Mg} / \mathrm{m}^{3}, \mu(\mathrm{MoK} \alpha)=0.944$ $\mathrm{mm}^{-1}, \mathrm{Mo} \mathrm{K} \alpha$ radiation, $\lambda=0.71073 \mathrm{~A}$, $\mathrm{GooF}=1.055$.

The structure of $\left[\mathrm{Co}(\mathrm{L})\left(\mathrm{NO}_{2}\right)_{3}\right]$ with $50 \%$ probability ellipsoid.

Keywords: Crystal structure; Boron coordination
compounds
A new complex 8 -aminoquinolinium bis(citrato)borate tetrahydrate $\mathrm{C}_{9} \mathrm{H}_{9} \mathrm{~N}_{2}\left[\left(\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{7}\right)_{2} \mathrm{~B}\right] \cdot 4 \mathrm{H}_{2} \mathrm{O}$ has been synthesized [1] in continuation of the systematic crystal chemical investigations of boron coordination compounds with organic cations. Well-shaped single crystals of it have been obtained and their full X-ray structural investigation has been carried out. The crystal structure is formed from univalent cations (HL) ${ }^{+}$, spiran-type complex anions $\left[\left(\mathrm{C}_{6} \mathrm{H}_{6} \mathrm{O}_{7}\right)_{2} \mathrm{~B}\right]^{-}$and four crystallization water molecules. The complex anions are formed

by two citric acid residues bidentatically coordinated to the central symmetrical distorted $\mathrm{BO}_{4}$ tetrahedron. The bonds B-O(carb.) (aver. 1.494(3) $\AA$ ) are systematically longer than B-O(hydr.) (aver. 1.461(3) $\AA$ ). The heterocyclic bond angles at boron atom ( $104.47(16)^{0}$ in average) are the smallest ones from the other O-B-O angles $\left(112.03(17)^{0}\right.$ in average). The average bond lengths within the citric acid residue: $\mathrm{C}\left(\mathrm{sp}^{3}\right)-\mathrm{O}(\mathrm{H})$ 1.417(3); in the terminal carboxyl groups $\mathrm{C}\left(\mathrm{sp}^{2}\right)=\mathrm{O}$ aver. $1.206(4), \mathrm{C}\left(\mathrm{sp}^{2}\right)-\mathrm{OH} 1.316(4) \AA$. The length of the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{C}\left(\mathrm{sp}^{3}\right)-\mathrm{C}\left(\mathrm{sp}^{3}\right)$ type is $1.538(3) \AA$; that of $\mathrm{C}\left(\mathrm{sp}^{2}\right)-\left(\mathrm{sp}^{3}\right) 1.496(4)$ A. The boron-containing five-membered rings C-O-B-O-C are planar in the limits of $\pm 0.02 \AA$. The oxygen atoms in carbonyl groups adjacent to heterocyclic system are coplanar to the atoms of cycle. The dihedral angle corresponding to the crossing of two main mean-square planes of heterocycles is $92.35(10)^{\circ}$. The cation is protonated at the nitrogen atom $\mathrm{N}(1)$. The values of the distances $\mathrm{N}-\mathrm{C}$ are: $\mathrm{N}(1)-\mathrm{C}(1) 1.330(5) \AA$; $\mathrm{N}(1)-\mathrm{C}(9)$ 1.361(4) $\mathrm{A} ; \mathrm{C}(\operatorname{ar})-\mathrm{N}(2) \mathrm{H}_{2}-1.335(5) \AA$. The quinolinate rings are planar in the limits of $\pm 0.01 \AA$. Amino group is declined from the plane by $0.10 \AA$. All four water molecules, all hydroxyl groups of complex anion terminal carboxyl groups, amino group and protonated nitrogen atom participates in fashion of the hydrogen bond system. Crystals are triclinic, space group P $\overline{1}$ : $a=9.601$ (1) $\AA, b=10.688(2) \AA, c=15.608(3) \AA ; \alpha=88.568(1)^{0}, \beta=76.740(1)^{0}$, $\gamma=63.523(2)^{0} ; \quad \mathrm{V}=1389.9(3) \quad \AA^{3} ; \quad \mathrm{Z}=2 ; \quad \mathrm{d}_{\mathrm{x}}=1.453 \quad \mathrm{gcm}^{-3}$; $\mathrm{R}=0.0433$, wR $2=0.0897$ for 3467 independent reflections with $\mathrm{I} \geq 2 \sigma(\mathrm{I})$ (MoK $\alpha$ radiation).
