A systematic study is reported of the products of the nucleophilic substitution reactions of the spermine-bridged cyclotriphosphazene, $[\text{N}_3\text{P}_3\text{X}_4(\text{NHCH}_2\text{CH}_2\text{CH}_2\text{N})\text{CH}_2\text{CH}_2]_2$ [where $X = \text{Cl}$ (*2a*)], to give a number of new structures [(*2b*)–(*2g*)] in which $X = \text{OPh}$, [spiro- $\text{O}(\text{CH}_2)_3\text{O}$]_{0.5}, Ph, NHPH, NC_4H_8 and NHBU^t , respectively. A comparison has been made between the sum of the substituent basicity constants, $\Sigma\alpha_R$, obtained in nitrobenzene solution, and ten molecular parameters of the N_3P_3 ring (the internal bond angles α , β , γ , δ and θ , and the P–N bond lengths a , b , c , d and e) as well as the difference between the bond lengths a and b , $\Delta(\text{P–N})$. It is found that the systematic change in molecular parameters of compounds (*2a*)–(*2g*) is in line with changes in α_R values, indicating the similarity in relative electron-releasing capacity of substituents X in the solid state and in solution. It is also found that the effect on molecular parameters of (*2a*)–(*2g*) with two X substituents in PX_2 groups is greater than that for one X substituent in $\text{P}(\text{OR})\text{X}$ groups in an analogous series of compounds observed previously [Bešli *et al.* (2002). *Acta Cryst.* **B58**, 1067–1073].

1. Introduction

Changes in molecular parameters of a series of compounds {2,6-di-*X*-4,4-diphenyl-2,6-(3,6,9-trioxaundecane-1,11-dioxy)-cyclotriphosphazene, where $X = \text{phenoxy}$ (*1a*), phenoxy (*1b*), methoxy (*1c*), anilino (*1d*), *tert*-butylamino (*1e*); 7,7'-butane-1,4-diylbis(2,2,2',2',4,4,4',4'-octa-*X*-1,3,5,7,11-pentaaza-2,4,6-triphosphaspiro[5.5]undecane), where $X = \text{chloro}$ (*2a*), phenoxy (*2b*), *kis*(3-hydroxypropoxy) (*2c*), phenyl (*2d*), anilino (*2e*), pyridino (*2f*), *tert*-butylamino (*2g*)} should reflect changes in electron distribution resulting from different substituents in the molecules. This expectation was confirmed for a series of molecules in which the two non-geminal Cl atoms adjacent to the *cis-ansa* macrocycle in the cyclotriphosphazene $\text{N}_3\text{P}_3\text{Ph}_2[\text{O}(\text{CH}_2\text{CH}_2\text{O})_4]\text{X}_2$ (*1*), $X = \text{Cl}$) were replaced by other groups ($X = \text{OCH}_2\text{CF}_3$, OPh, OMe, NHPH and NHBU^t), see (I); the molecular parameters of (*1a*)–(*1e*) were related to the sum of the basicity constants, $\Sigma\alpha_R$, of the substituents (Bešli *et al.*, 2002). The changes in substituent basicity constants, α_R , are indicative of changes in electron distribution (Feakins *et al.*, 1965, 1968; Feakins, Last *et al.*, 1969; Feakins, Shaw *et al.*, 1969), which is also reflected in the changes in molecular parameters. An approximate linear relationship was demonstrated between $\Sigma\alpha_R$ and selected bond lengths and angles of compounds (*1a*)–(*1e*) in which the

Computer programs used: DENZO (Otwinowski & Minor, 1997), COLLECT (Hooft, 1998), SHELXS97 (Sheldrick, 1997), SHELXL97 (Sheldrick, 1997), PLATON (Spek, 1990).

substituent X varies in the moiety $PX(Om)$ (m = macrocycle; Bešli *et al.*, 2002, Part 5 of the series).

In the present study we report on changes in analogous molecular parameters in the series of tetra-substituted spermine-bridged cyclotriphosphazenes $[N_3P_3X_4(NHCH_2CH_2-CH_2N)CH_2CH_2]_2$, (2) {where $X = Cl, OPh, [spiro-O(CH_2)_3O]_{0.5}, Ph, NHPh, pyr$ (pyrrolidino) and $NHBU^t$ for (2a)–(2g) respectively}, see (1). For (2a)–(2g) the X substituent varies for the moiety PX_2 , where two geminal substituents are replaced on one P atom, compared with the replacement of one X substituent on one P atom in (1a)–(1e).

2. Experimental

2.1. Preparation of compounds

Compounds (2b), (2c), (2e) and (2f) were synthesized by reaction of the known compound (2a) (Labarre *et al.*, 1984) with an excess of the appropriate nucleophile (phenol, 1,3-propanediol, aniline and pyrrolidine, respectively), whereas

Figure 2
The molecular structure of (2c).

Figure 3
The molecular structure of (2d) with the benzene solvate molecule removed for clarity.

Figure 4
The molecular structure of compound (2e) with water molecules omitted for clarity.

(2d) and (2g) were synthesized by reaction of spermine with the known di-gem, tetra-substituted cyclophosphazene precursors 2,2-dichloro-4,4,6,6-tetraphenylcyclophosphazene (Acock *et al.*, 1964) and 2,2-dichloro-4,4,6,6-tetra-*tert*-butylaminocyclophosphazene (Das *et al.*, 1965). Full details of the synthetic procedures for (2b)–(2g) are being reported elsewhere (Yenilmez-Çiftçi, 2004).

2.2. Crystallography

Data were collected at 120 K on an Nonius KappaCCD area-detector diffractometer located at the window of a Nonius FR591 rotating anode X-ray generator, equipped with a molybdenum target [$\lambda(\text{Mo } K\alpha) = 0.71073 \text{ \AA}$]. Structures were solved and refined using the *SHELX97* (Sheldrick, 1997) suite of programs. Data were corrected for absorption effects by comparing equivalent reflections using the program *SORTAV* (Blessing, 1997). Non-H atoms were refined anisotropically, whilst H atoms were generally fixed in idealized positions (with the exception of some N–H protons, whose positions were determined from a difference map) with their displacement parameters riding on the values of their parent atoms. The structure of (2e) contains a disordered water molecule split over two sites, neither of which could be assigned reliably with H atoms, and the structure of compound (2d) contains a benzene solvate molecule. There are a number of potentially serious validation errors, mainly for structures (2c), (2e) and (2f), which are discussed below:

(i) The crystal of (2c) used in the experiment was a small platelet of the dimensions $0.12 \times 0.08 \times 0.03 \text{ mm}$, which diffracted weakly and only achieved a data completeness of 93%, despite 40 second exposure times for each image.

(ii) The amido H atoms on atoms N4 and N13 of (2e) were somewhat poorly defined in the difference map and had to be restrained in the model to conform to a regular geometry.

(iii) The crystal quality of (2f) was extremely poor (fibrous needle $0.24 \times 0.05 \times 0.03 \text{ mm}$), resulting in a weak diffraction pattern that did not extend to high angles and could only produce a very limited dataset. The structure derived for (2f)

from this data is somewhat poor, however, the core N_3P_3 rings and areas of interest in the molecular structure are defined reasonably well and the structure is considered to be pertinent and important to this study and is therefore included. Pertinent data collection and refinement parameters are collated in Table 1.¹ The data for (2a) were extracted from the Cambridge Structural Database (Allen *et al.*, 1983) as a CIF, with the refcode COPTUW (Labarre *et al.*, 1984).

3. Results

3.1. Molecular structures

Displacement ellipsoid plots for (2b)–(2g) [see (I)] are shown in Figs. 1–6, respectively. The common factors between all seven molecular systems are the facts that the halves of the bridged molecule have the same substitution pattern in each N_3P_3 ring, and that one P atom in

¹ Supplementary data for this paper are available from the IUCr electronic archives (Reference: BM5015). Services for accessing these data are described at the back of the journal.

Table 2

Parameters of the molecular frameworks of (2a)–(2g) defined in Fig. 8.

$\Sigma\alpha_R$ = sum of substituent basicity constants; $\Delta(P-N) = a - b$; ΣNH_{sp} and ΣNC_{sp} are the sums of three internal bond angles for the N atoms of NH_{sp} and NC_{sp} , respectively. The spiro ring puckering amplitude is derived by standard methods (Cremer & Pople, 1975). Conformation corresponds to the *syn* or *anti* conformation of the cyclophosphazene rings about the $NCH_2CH_2CH_2CH_2N$ bridge. Values of molecular parameters for (2a) are taken from Labarre *et al.* (1984).

each N_3P_3 ring has a common pair of substituents consisting of a six-membered spiro ring with one primary and one secondary N atom joined at one end by the P atom and linked at the other by a trimethylene chain, $CH_2CH_2CH_2$. These spiro rings all adopt a chair configuration. The other two P atoms in (2a)–(2g) have the same substituents (X_2) on each P atom in each N_3P_3 ring, in which *X* differs from compound to compound. The bridging moiety consists of a five-bond chain, $NCH_2CH_2CH_2CH_2N$, about which rotation can occur and giving, in principle, a range of conformations for the two cyclophosphazene rings with respect to each other. In practice it is found that the two substituted cyclophosphazene rings take up either *syn* or *anti* conformations; (2a), (2b), (2d), (2e) and (2g) adopt an *anti* conformation, whilst (2c) and (2f) are present as *syn* conformers. In (2b) two non-geminal OPh (O2 and O3) groups adopt a conformation above the N_3P_3 ring, making them almost parallel. However, with a centroid separation of approximately 4.2 Å this is most likely to be a packing effect. In the *anti* structures (2a) and (2b) the two N_3P_3 rings are in almost parallel planes, whilst in the *syn* structures (2c) and (2f) the two N_3P_3 rings are slightly tilted

towards each other. The tetramethylene chain, $CH_2CH_2CH_2CH_2$, bridging the two cyclophosphazene rings exhibits a near zigzag structure in all compounds, except in the *syn* conformer (2c), where it is rather distorted. The structures of partially substituted spermine-bridged derivatives have been reported previously: whilst those with Ph groups mirrored the *anti* conformation of its per-substituted derivative (2d) (Coles *et al.*, 2001), interestingly those with spiro-[$O(CH_2)_3O$] [where spiro = $-NH(CH_2)_3N(CH_2)_4N(CH_2)_3HN-$] and NHBu^t substituents (Bešli *et al.*, 2003) had the opposite conformation from those of their per-derivatives [(2c), *syn*] and NHBu^t [(2g), *anti*], respectively. From Table 2 one can see that these compounds exhibit both *syn* and *anti* conformations. Further work to rationalize this observation is currently in progress.

3.2. Crystal structures

The hydrogen-bonding schemes for (2a)–(2g) are summarized in Fig. 7. In (2a) and (2c) the N–H of the spiro group

bonds to a ring N atom in another molecule. This occurs in both halves of the molecule and leads to infinite ladders linked by single hydrogen bonds, where the rungs are the tetra-

methylene chains, $CH_2CH_2CH_2CH_2$. In (2b) and (2d) the N—H of the spiro group bonds to a ring N atom in another molecule. In this case, however, the two molecules form eight-membered hydrogen-bonded rings. Again leading through the other half of the molecule to infinite chains, which are held by two hydrogen bonds, in this case there is no ladder arrangement as both hydrogen bonds are involved in the eight-membered rings. The hydrogen bonding in (2e) is complex, involving mainly the N—H parts of the NHPPh groups. The strongest of these interactions are two N—H...N bonds with a phosphazene ring N atom, which forms a zigzag chain. This chain then interacts through close contacts and weaker hydrogen bonds with other chains and the water molecules to form a sheet-like structure. In (2f) the situation is also complicated. Two molecules bind together as head-to-tail dimers through hydrogen bonding (C18...N12 and C25...N1). This association facilitates N—H...N interactions, where the N13—H of the spiro group of one molecule (A) bonds intramolecularly to the secondary N atom (N4) of the spiro group of another molecule (B). This other molecule (B)

Figure 7
Hydrogen-bonding schemes for (2a)–(2g).

in turn forms a bifurcated hydrogen bond from N14B to a ring N atom, N1 in molecule *A*, as well as to the secondary N atom (N5) of the spiro group of molecule *A*. In (2*g*) there are again eight-membered hydrogen-bonded rings, which differ from those in (2*b*) and (2*c*) in that the N—H of the spiro group does not bond to a ring N atom in another molecule, but to the secondary N atom of the spiro group forming an infinite zigzag structure. Interestingly, the N—H of the NHBu' groups in (2*g*) do not form any significant hydrogen bonds.

4. Discussion

Early crystallographic studies have provided evidence that cyclotriphosphazenes carrying two or more different substituents show significant differences in bond lengths (Mani *et al.*, 1965, 1966; Allen *et al.*, 1969; Ahmed & Pollard, 1972; Ahmed & Gabe, 1975; Ahmed & Fortier, 1980) and later studies revealed trends in both bond lengths and angles, which could

be related to a variety of different physical and chemical properties (Contractor *et al.*, 1985; Fincham *et al.*, 1986; Alkubaisi *et al.*, 1988). It is known that substituent basicity constants give a reliable indication of the relative electron-releasing capacity of different substituent *X* groups (Feakins *et al.*, 1965; Feakins, Last *et al.*, 1969; Feakins, Shaw *et al.*, 1969) and it was found that changes in bond lengths and angles of the series of cyclotriphosphazene derivatives (1*a*)–(1*e*) varied with the sum of the substituent basicity constants $\Sigma\alpha_R$ (Bešli *et al.*, 2002). A similar analysis is made for (2*b*)–(2*g*) in this work and the results are compared with those for (2*a*) (Labarre *et al.*, 1984).

The structural parameters considered for (2*a*)–(2*g*) are the bond lengths (*a*, *b*, *c*, *d* and *e*) and angles (α , β , γ , δ and θ), which are defined in the generalized structure for (2) shown in Fig. 8. The structural data for (2*a*)–(2*g*) summarized in Table 2 show a small, but moderately consistent, trend of bond lengths and angles in the series of molecules which reflects the elec-

Figure 7 (continued)

tron-releasing capacity of the substituents $X = \text{Cl}$, OPh , [spiro- $\text{O}(\text{CH}_2)_3\text{O}]_{0.5}$, Ph , NHPh , pyr and NHBu^t . The values of the sum of the substituent basicity constants, $\Sigma\alpha_R$, for (2a)–(2g) are also summarized in Table 2. In general it is found that, with the increasing value of $\Sigma\alpha_R$, the bond angles α and δ increase, whilst those for β , γ and θ decrease; concomitantly, the bond length a decreases, whilst b , c , d and e increase. Although the present structural data refer to molecules in their unperturbed ground state in the crystalline solid and the basicity measurements were made in nitrobenzene solution (Feakins *et al.*, 1965, 1968; Feakins, Last *et al.*, 1969; Feakins, Shaw *et al.*, 1969), where the molecule is perturbed by the approach of a proton (Koppel *et al.*, 2001), there is a definite relationship between the molecular parameters of (2a)–(2g) and the substituent basicity constant, analogous to the effects observed previously (Bešli *et al.*, 2002). Other molecular parameters, such as $\Delta(\text{P–N})$ values and the sum of the bond angles $\Sigma\text{NH}sp$ and $\Sigma\text{NC}sp$ in the series of molecules (2a)–(2g), also decrease as $\Sigma\alpha_R$ increases, indicating a similar trend in increasing electron density provided by the X substituents, from $X = \text{Cl}$ through to $X = \text{NHBu}^t$.

The results on the variation of molecular parameters with two substituents in PX_2 groups in (2a)–(2g) can be compared with previous work (Bešli *et al.*, 2002) on the variation of molecular parameters with one substituent X in $\text{PX}(\text{OR})$ groups of (1) (Fig. 8). The difference in molecular parameters of (2g), $X = \text{NHBu}^t$, $\Sigma\alpha_R = 23.6$, and (2a), $X = \text{Cl}$, $\Sigma\alpha_R = 0$, is summarized in Table 3, together with the values for the analogous compounds (1). It can be seen that for each parameter the sign of the difference is the same in the two series, but the magnitude of the change is greater for (2) than for (1). Given the changes in the basic molecular structure in which a PPh_2 moiety in (1) is replaced by a nitrogenous spiro group compound (2) and the presence of the macrocyclic ring in (1), these results are consistent with a larger change in molecular parameters in those of (2) with two substituents in PX_2 groups compared with those of (1) having one substituent X in $\text{P}(\text{OR})\text{X}$ groups.

We have also compared the values of the difference in bond lengths, $\Delta(\text{P–N})$, resulting from substitution in the cyclo-

phosphazene ring (Bešli *et al.*, 2002). The choice of the two bond lengths which are subtracted from each other is somewhat arbitrary (other than being adjacent P–N bonds), but $\Delta(\text{P–N})$ must be consistent for the set of compounds discussed and compared. In the present context, $\Delta(\text{P–N})$ is taken as bond lengths $a-b$, as defined in Fig. 8. Again, it is shown in Table 3 that there is a greater change in $\Delta(\text{P–N})$ for (2) with two X substituents per P atom compared with those of (1) having one substituent X .

5. Conclusions

Structural investigations of the molecular framework [bond angles α , β , γ , δ and θ , and bond lengths a , b , c , d and e , as well as $\Delta(\text{P–N})$ values] of (2a)–(2g) have revealed a fairly consistent trend of changes in molecular parameter, which mirror the electron release of the substituents X , as measured by basicity measurements in nitrobenzene solution. The changes in molecular parameters reported here for two digeminal substituted X_2 groups (*i.e.* four substituents) are approximately twice those observed in an earlier study, where two non-geminal substituents X (*i.e.* two substituents) were varied. Ellipsoids are displayed at the 50% level in this and the following five figures, except where noted.

The authors would like to thank the EPSRC for funding the National Crystallographic Service (Southampton, England), the Shin Nisso Kako Co Ltd for gifts of $\text{N}_3\text{P}_3\text{Cl}_6$, the Gebze Institute of Technology (GIT) Research Fund for partial support (GYÇ and AK).
