# Clarifying the structures of imidines: using crystallographic characterization to identify tautomers and localized systems of $\pi$-bonding 

Michael M. Aristov, Han Geng, James W. Harris and John F. Berry*

Department of Chemistry, University of Wisconsin-Madison, 1101 University Ave, Madison, WI 53703, USA. *Correspondence e-mail: berry@chem.wisc.edu

Nitrogen heterocycles are a class of organic compounds with extremely versatile functionality. Imidines, $\mathrm{HN}[\mathrm{C}(\mathrm{NH}) R]_{2}$, are a rare class of heterocycles related to imides, $\mathrm{HN}[\mathrm{C}(\mathrm{O}) R]_{2}$, in which the O atoms of the carbonyl groups are replaced by $\mathrm{N}-\mathrm{H}$ groups. The useful synthesis of the imidine compounds succinimidine and glutarimidine, as well as their partially hydrolyzed imino-imide congeners, was first described in the mid-1950s, though structural characterization is presented for the first time in this article. In the solid state, these structures are different from the proposed imidine form: succinimidine crystallizes as an imino-amine, 2-imino-3,4-dihydro-2H-pyrrol-5-amine, $\mathrm{C}_{4} \mathrm{H}_{7} \mathrm{~N}_{2}$ (1), glutarimidine as 6-imino-3,4,5,6-tetrahydropyridin-2-amine methanol monosolvate, $\mathrm{C}_{5} \mathrm{H}_{9} \mathrm{~N}_{3} \cdot \mathrm{CH}_{3} \mathrm{OH}$ (2), and the corresponding hydrolyzed imino-imide compounds as amino-amides 5-amino-3,4-dihydro-2H-pyrrol-2-one, $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{~N}_{2} \mathrm{O}$ (3), and 6-amino-4,5-dihydropyridin-2(3H)-one, $\mathrm{C}_{5} \mathrm{H}_{8} \mathrm{~N}_{2} \mathrm{O}$ (4). Imidine 1 was also determined as the hydrochloride salt solvate 5-amino-3,4-dihydro- 2 H -pyrrol-2iminium chloride-2-imino-3,4-dihydro-2 H -pyrrol-5-amine-water (1/1/1), $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{~N}_{3}{ }^{+}$.-$\mathrm{Cl}^{-} \cdot \mathrm{C}_{4} \mathrm{H}_{7} \mathrm{~N}_{3} \cdot \mathrm{H}_{2} \mathrm{O}(\mathbf{1} \cdot \mathrm{HCl})$. As such, $\mathbf{1}$ and $\mathbf{2}$ show alternating short and long $\mathrm{C}-\mathrm{N}$ bonds across the molecule, revealing distinct imino $(\mathrm{C}=\mathrm{NH})$ and amine $\left(\mathrm{C}-\mathrm{NH}_{2}\right)$ groups throughout the $\mathrm{C}-\mathrm{N}$ backbone. These structures provide definitive evidence for the predominant imino-amine tautomer in the solid state, which serves to enrich the previously proposed imidine-focused structures that have appeared in organic chemistry textbooks since the discovery of this class of compounds in 1883.

## 1. Introduction

Nitrogen heterocycles are of considerable interest for their ability to act as ligands in coordination chemistry, notably supporting multimetallic compounds and, in particular, compounds having metal-metal bonds (Chipman \& Berry, 2020; Beach et al., 2021; Kerru et al., 2020). Examples of these types of ligands can be seen in 2-naphthyridylphenylamine (Ding et al., 2015; Liu, Wang et al., 2009; Liu, Chen et al., 2009; Tsai et al., 2013), 1,8-naphthyridin-2(1H)-one (Chang et al., 2017), 2-anilinopyridinate (Roy et al., 2022) and 2,2'-dipyridylamine (Hdpa) (Chipman \& Berry, 2018a,b; Lescouëzec et al., 2001; Berry et al., 2003; Hsiao et al., 2008).

We have recently explored the ability of the ligand $2,2^{\prime}$ dipyridylamine (Scheme 1 shows the structures of Hdpa, succinimide, the proposed 'succinimidine' structure, and the observed structure of $\mathbf{1}$ ) to support linear trimetallic metal-metal-bonded compounds (Brogden \& Berry, 2016). In the search for other multitopic $N$-donor ligands that might support similar structures, our attention was drawn to the class of compounds called 'imidines', first described by Pinner in 1883 (Pinner, 1883) and then later by Elvidge and Linstead in
the 1950s. In particular, we focus on the heterocyclic compounds 'succinimidine' and 'glutarimidine' (Elvidge et al., 1959; Elvidge \& Linstead, 1954). These compounds were so named because of their proposed structural analogy to succinimide (Scheme 1) and the corresponding six-memberedring analog glutarimide. Since imidines represent a relatively rare functional group, these structures, proposed solely on the basis of elemental analysis results, have been propagated in prominent organic chemistry textbooks (March, 1992). We show here that although solution-based studies agree with the historically predicted imidine tautomers, in the solid state, the compounds 'succinimidine' and 'glutarimidine' adopt a different tautomeric form from those originally proposed. In the solid state, the structures are unsymmetric imino-amines and are better named systematically as 2 -imino-3,4-dihydro- 2 H -pyrrol-5-amine (1) and 6-imino-3,4,5,6-tetrahydropyridin-2amine (2).

Succinimide

1

Scheme 1

The 1950s syntheses involved the reaction of methanol solutions of terminal dinitriles (succinonitrile, glutaronitrile, or adiponitrile) with liquid ammonia before heating (Elvidge \& Linstead, 1954; Elvidge et al., 1959). We have found that similar results can be obtained by saturating a methanol solution of succinonitrile with anhydrous ammonia. This solution, when heated for 18 h in a sealed bomb flask, yielded $\mathbf{1}$ in $>50 \%$ yield. The product is easily separated from the mother liquor by precipitation via the addition of excess diethyl ether. The synthesis of $\mathbf{2}$ was performed in an almost identical manner; however, to achieve a useful yield, the reaction mixture was heated for 40 h total. The solvent was then removed by rotary evaporation and yellow crystals separated from the residual oil, which was washed away with ether. The modified Pinner reaction conditions result in protio-neutral ring closing to yield the N -heterocycle with two additional N -atom-based functional groups. Both the original article from Pinner and the later articles from Elvidge and Linstead draw all three N -atom sites as being singly protonated in a symmetric 'imidine' form (Pinner, 1883; Elvidge \& Linstead, 1954; Elvidge et al., 1959). Elvidge and Linstead additionally reported that reaction of the imidines with water sequentially replace one and then both terminal N -atom functional groups with carbonyl groups, such that 'succinimidine' could be fully hydrolyzed to form succinimide (Elvidge \& Linstead, 1954; Elvidge et al., 1959). While the symmetric structure of succinimide in the solid state is well established
(Yu et al., 2012; Mason, 1961), the monohydrolyzed forms of $\mathbf{1}$ and 2 have not been investigated before, and they are structurally characterized here (Scheme 2 shows the structures of the most stable solid-phase tautomers of the species described

in this article, with only one resonance structure being shown for the protonated species found in $\mathbf{1} \cdot \mathbf{H C l}$ ). A combination of solid state, solution, and computational studies are employed to best describe the various possible tautomers of these species.

## 2. Experimental

### 2.1. General methods

Methanol (Sigma-Aldrich) was distilled from $\mathrm{CaH}_{2}$ under $\mathrm{N}_{2}$ and used immediately. Succinonitrile and glutaronitrile were purchased from Sigma-Aldrich and used as received. Inhibitor-free anhydrous diethyl ether was purchased from Sigma-Aldrich and used as received. All deuterated solvents were purchased from Sigma-Aldrich, used as received, and stored long term in air. Unless otherwise noted, all manipulations were performed in air. Electrospray ionization mass spectrometry was performed with a Thermo Q Exactive Plus mass spectrometer. IR spectra were recorded with a Bruker Tenser 27 spectrometer using an ATR adapter. ${ }^{1} \mathrm{H}$ NMR spectra were recorded on a 400 MHz Bruker Avance III spectrometer. Caution! The synthetic procedures for the preparation of $\mathbf{1}$ and $\mathbf{2}$ involve heating a sealed reaction vessel and should only be performed at or below the scale described here using rated thick-walled glassware, with a protective blast shield.

### 2.2. Synthesis and crystallization

2.2.1. Synthesis of 1 . Imidine $\mathbf{1}$ was synthesized through a modification of the literature procedure of Elvidge \& Linstead (1954). Anhydrous methanol ( 70 ml ), succinonitrile ( 4.02 g , 50.1 mmol ), and a Teflon stirrer bar were combined in a 250 ml heavy-walled threaded glass vessel. The solid was fully dissolved and the resulting solution was sparged with anhydrous ammonia gas until saturated. The flask was then tightly sealed and partially submerged in an oil bath. The oil bath was programmed to heat to $70^{\circ} \mathrm{C}$ for 18 h before automatically cooling to room temperature. A blast shield was placed in front of the flask and the heating cycle was started. Upon cooling to room temperature, the pressure flask containing a

Table 1
Experimental details.
Experiments were carried out at 100 K using a Bruker SMART APEXII (Quasar) diffractometer. H atoms were treated by a mixture of independent and constrained refinement. Absorption was corrected for by multi-scan methods (SADABS; Bruker, 2016; Krause et al., 2015).

Computer programs: APEX3 (Bruker, 2016, 2017), SAINT-Plus (Bruker, 2016), SAINT (Bruker, 2017), olex2.solve (Bourhis et al., 2015), SHELXT (Sheldrick, 2015a), SHELXL2018 (Sheldrick, 2015b) and OLEX2 (Dolomanov et al., 2009).
black solution was removed from the oil bath. Activated carbon $(\sim 3 \mathrm{~g})$ was added to the solution, which was sparged with nitrogen for 10 min . The solution was then filtered through Celite to yield a pale-yellow filtrate. This filtrate was added to diethyl ether ( 300 ml ), resulting in precipitation of the product. The suspension was filtered through a glass frit and the off-white solid was washed several times with ether.

The solid was dried under high-vacuum overnight and stored in a nitrogen glove-box without further purification. X-rayquality crystals were obtained by slow diffusion of diethyl ether into a saturated solution of $\mathbf{1}$ in MeOH under an inert atmosphere. ESI $(\mathrm{m} / \mathrm{z}):\left([M+\mathrm{H}]^{+}\right)$98.0712. IR (ATR, $\left.\mathrm{cm}^{-1}\right)$ : 3289, 3157, 3077, 2935, 2847, 1829, 1772, 1749, 1686, 1662, 1654, $1636,1532,1473,1453,1418,1328,1296,1265,1241,1223,1190$,
$1143,1129,1115,996,936,919,851,822,783,665,651,641 .{ }^{1} \mathrm{H}$ NMR (400 MHz, DMSO): $\delta 7.37(s, 3 H), 2.46(s, 4 H)$. Crystals of $\mathbf{1} \cdot \mathrm{HCl}$ were fortuitously obtained by slow diffusion of diethyl ether into a deuterated chloroform solution containing 1 (yield: $2.46 \mathrm{~g}, 25.3 \mathrm{mmol}, 50.6 \%$ ).
2.2.2. Synthesis of 2. Imidine 2 was synthesized by a modified literature method (Elvidge \& Linstead, 1954). Anhydrous methanol ( 70 ml ), glutaronitrile $(2.0299 \mathrm{~g}$, 21.568 mmol ), and an oven-dried stirrer bar were added to an oven-dried pressure flask under a constant stream of nitrogen gas. The resulting solution was sparged with nitrogen gas for 5 min and then saturated with ammonia gas. The flask was then sealed and heated at $70^{\circ} \mathrm{C}$ for 40 h while stirring. Once the flask had cooled, the clear solution was sparged with nitrogen for $\sim 20 \mathrm{~min}$. The solvent was removed via rotary evaporation. The resulting yellow powder was washed with diethyl ether and filtered to remove residual glutaronitrile. X-ray-quality crystals were obtained by evaporation of a saturated MeOH solution (yield: $0.760 \mathrm{~g}, 31.7 \%$ ). ESI ( $\mathrm{m} / \mathrm{z}$ ): $\left([M+\mathrm{H}]^{+}\right) 112.0868$. IR (ATR, $\left.\mathrm{cm}^{-1}\right): 3254,3004,2954,1666$, $1605,1543,1457,1418,1373,1334,1316,1316,1187,1145,1103$, 1061, 967, 909, 886, 791, 758, 676. ${ }^{1} \mathrm{H}$ NMR ( 400 MHz , DMSO): $\delta 7.05(s, 3 H), 2.20(t, J=6.5 \mathrm{~Hz}, 4 \mathrm{H}), 1.80-1.57(q$, 2H).
2.2.3. Synthesis of 3 . A scintillation vial was charged with $\mathbf{1}$ $(1.0 \mathrm{~g}, 0.010 \mathrm{~mol})$. Milli-Q water $\left(3.4 \mathrm{ml}, 0^{\circ} \mathrm{C}\right)$ was then added to the vial, immediately turning the solution faint brown. The
vial was stored in a $0{ }^{\circ} \mathrm{C}$ refrigerator overnight. The next day, white crystals (yield: $0.68 \mathrm{~g}, 0.0069 \mathrm{~mol}, 69 \%$ ) suitable for X-ray diffraction analysis were collected from the solution. ESI $(m / z):\left([M+\mathrm{H}]^{+}\right) 99.0552$. IR (ATR, $\left.\mathrm{cm}^{-1}\right): 3220,3135$, 3019, 2938, 2918, 2851, 2360, 2341, 1686, 1627, 1526, 1456, 1437, 1418, 1397, 1338, 1294, 1251, 1221, 1161, 1009, 929, 866, 852, 827, 765, 677. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{DMSO}$ ): $\delta 8.30(s, 1 \mathrm{H}), 8.07$ $(s, 1 \mathrm{H}), 2.67-2.56(m, 2 \mathrm{H}), 2.34-2.25(m, 2 \mathrm{H})$.
2.2.4. Synthesis of 4. A scintillation vial was filled with 2 $(0.10 \mathrm{~g}, 0.90 \mathrm{mmol})$ and the solid was subsequently dissolved in a minimal amount of Milli-Q water. The resulting solution was cooled overnight before allowing ether vapor to diffuse into the solution. The product precipitated out as white crystals (yield $0.048 \mathrm{~g}, 47 \%$ ) suitable for X-ray diffraction, with a minor impurity of 6-hydroxy-4,5-dihydropyridin-2(3H)-one. ESI $(m / z):\left(\left[M+\mathrm{NH}_{4}\right]^{+}\right): 130.0975$. IR (ATR, $\left.\mathrm{cm}^{-1}\right): 3381$, 3185, 2967, 2947, 2920, 2886, 2823, 2774, 1644, 1534, 1506, 1458, $1426,1418,1349,1299,1274,1222,1153,1120,1071,1056,948$, 917, 864, 807, 756, 671, 638. ${ }^{1} \mathrm{H}$ NMR ( 400 MHz, DMSO- $d_{6}$ ): $\delta$, $7.35(s, 1 \mathrm{H}), 6.80(s, 1 \mathrm{H}), 2.24(t, J=7.7 \mathrm{~Hz}, 2 \mathrm{H}), 1.88(t, J=$ $7.3 \mathrm{~Hz}, 2 \mathrm{H}$ ), 1.78 (quint, $J=7.4 \mathrm{~Hz}, 2 \mathrm{H}$ ).

### 2.3. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. For the structures of $\mathbf{1}$ and 4, the diffraction data were consistent with a triclinic unit cell.

| $\mathbf{1} \cdot \mathrm{HCl}$ (neutral species) | 1.314 (3) | 1.323 (3) | 1.393 (3) | 1.274 (3) | 0.040 (6) | 0.070 (6) |
| 2 (upper) | 1.329 (2) | 1.316 (2) | 1.386 (1) | 1.280 (2) | 0.049 (4) | 0.070 (3) |
| 2 (lower) | 1.325 (2) | 1.323 (2) | 1.381 (2) | 1.289 (2) | 0.036 (4) | 0.058 (4) |
| 3 | 1.311 (2) | 1.333 (1) | 1.379 (2) | 1.231 (1) | - | 0.046 (3) |
| 4 | 1.315 (2) | 1.334 (1) | 1.366 (2) | 1.238 (1) | - | 0.032 (3) |

The $E$-statistics for $\mathbf{1}$ and $\mathbf{4}$ strongly suggested the centrosymmetric space group $P \overline{1}$, which yielded chemically reasonable and computationally stable refinements. For the structures of $\mathbf{2}, \mathbf{3}$, and $\mathbf{1} \cdot \mathrm{HCl}$, a combination of systematic absences in the diffraction data and the $E$-statistics were used to assign the centrosymmetric space groups $P 2_{1} / c, P 2_{1} / n$, and $C 2 / c$, respectively.

The structures were solved via intrinsic phasing and refined by least-squares refinement on $F^{2}$, followed by difference Fourier synthesis. All non-H atoms above $70 \%$ occupancy were refined with anisotropic displacement parameters. Unless otherwise stated, all H atoms were included in the final structure-factor calculations at idealized positions and were allowed to ride on their neighboring atoms with relative isotropic displacement coefficients. In the structure $\mathbf{1} \cdot \mathrm{HCl}$, all amine H atoms were fixed at idealized locations, where as the imidine and water H atoms were allowed to freely refine.

The coordinates of the H atoms bound to N atoms in $\mathbf{1}, \mathbf{3}$, and 4 were allowed to refine freely. In 2, residual electron density provided strong evidence for the coordinates of the N -atom-bound H atoms; however, there was not sufficient electron density to allow the H atoms to refine freely. As such, the coordinates of the H atoms bound to N atoms in 2 were fixed at idealized positions.

In the structure of $\mathbf{2}$, the three methylene C atoms of the ring are disordered over two positions, with a major occupancy of $85.4(6) \%$. The lesser fraction of the disordered part of the ring was restrained to the geometry of the major fraction of the same ring. One of the methanol solvent molecules exhibited disorder of the $\mathrm{CH}_{3}$ protons.

## 3. Results and discussion

### 3.1. Structural commentary

Three of the title N-heterocycles, namely, $\mathbf{1}, \mathbf{3}$, and $\mathbf{4}$, crystalize with only one molecule in the asymmetric unit, with no disorder or solvent molecules. The crystal structure for $\mathbf{2}$ includes two N-heterocycles and two methanol solvent molecules in the asymmetric unit. The two independent molecules of 2 (denoted 'upper' and 'lower') interact via a set of two $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds to form a dimeric structure. A similar structural motif is seen in the structure of succinimide (Yu et al., 2012; Mason, 1961) and for some of the other compounds described here, when looking at the structures beyond just the asymmetric unit (vide infra). Additionally, one
of the molecules of $\mathbf{2}$ displays disorder across the three $-\mathrm{CH}_{2}-$ units in the backbone, and one methanol molecule shows disorder of the H atoms on the $-\mathrm{CH}_{3}$ group. The structure of $\mathbf{1} \cdot \mathrm{HCl}$ contains one neutral five-membered heterocycle, its protonated species, a $\mathrm{Cl}^{-}$counter-ion, and one solvent water molecule. The asymmetric unit of each structure is shown in Fig. 1.

In 1, the NH protons are distributed such that one terminal N atom is doubly protonated as an amine, the N atom in the ring is not protonated, and the other terminal N atom is singly protonated, as an imine, with the proton pointing towards the hydrophobic backbone. In 2, the H atoms are distributed in a nearly identical manner. However, due to intermolecular $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ hydrogen-bonding interactions with the solvent methanol molecules, the imine N atom of each of the two independent molecules of $\mathbf{2}$ has its single H atom pointed away from the hydrophobic backbone. In both $\mathbf{3}$ and 4, the O atom binds as a carbonyl group, as indicated by the short $\mathrm{C}=\mathrm{O}$ distances of 1.231 (1) and 1.238 (1) $\AA$. As in the NNN structures, the N atom in the ring is not protonated, and the terminal N atom is doubly protonated as an amine. Crystals of $\mathbf{1} \cdot \mathrm{HCl}$ were obtained fortuitously from slow diffusion of diethyl ether into a solution of deuterated chloroform containing 1. In the structure of $\mathbf{1} \cdot \mathrm{HCl}$, there exists both a neutral species, comparable to the heterocycle found in $\mathbf{1}$, and a protonated cationic species where both terminal N atoms are doubly protonated, with the N atom in the ring being left unprotonated. The protonated species in $\mathbf{1} \cdot \mathrm{HCl}$ is balanced by a $\mathrm{Cl}^{-}$anion. The protonation states of all the complexes can be seen in Fig. 1. Notably, the protonation states of all the compounds differ from the structure of succinimide, which remains symmetric despite forming similarly asymmetric hydrogen-bonded dimers (Yu et al., 2012; Mason, 1961). The structures of $\mathbf{1}$ and $\mathbf{2}$ are also notably inconsistent with their earlier structural proposals as 'succinimidine' and 'glutarimidine', and it is particularly notable that protonation of $\mathbf{1}$ to form the HCl salt occurs at a terminal imine rather than the

internal ring position. These observations are consistent with $\mathrm{p} K_{a}$ data for terminal versus internal imines: $(\mathrm{Ph})_{2} \mathrm{C}=\mathrm{NH}$ $\left(\mathrm{p} K_{a}=31.0\right)$ (Bordwell \& Ji, 1991) and $\mathrm{PhCH}_{2} \mathrm{~N}=\mathrm{C}(\mathrm{Ph})_{2}$ ( $\mathrm{p} K_{a}=24.3$ ) (Bordwell, 1988).

The proposed protonation states of 1-4 are further supported by the bond lengths across the heteroatoms, as seen in Fig. 2. These bond distances, as well as relevant comparisons, are given in Table 2. We note the neutral compounds show statistically meaningful differences between the A/D and B/C bond pairs defined in Fig. 2. Specifically, these differences appear to indicate a localized $\pi$-system with alternating single and double bonds, where the shorter bonds are localized to B

and D. In contrast, these differences in the structure of the protonated species of $\mathbf{1} \cdot \mathrm{HCl}$ are statistically insignificant. Thus, the structure of the protonated species in $\mathbf{1} \cdot \mathbf{H C l}$ is best described by a delocalized electronic structure which could be represented by the two limiting resonance forms shown in Scheme 3. Notably, the neutral species in $\mathbf{1} \cdot \mathrm{HCl}$ shows nearly identical differences in the bond lengths to those in $\mathbf{1}$. Notably, the neutral molecule in $\mathbf{1} \cdot \mathrm{HCl}$ and in $\mathbf{2}$ show an alternate binding motif for the imine-bound proton observed in $\mathbf{1}$. This alternative binding motif likely arises from the hydrogenbonding interaction blocking the other side of the imine.

To gain further insights into the protonation states of $\mathbf{1}$, computational studies were performed. All calculations were carried out using GAUSSIAN16 (Frisch et al., 2016), HartreeFock theory, and the $6-31 \mathrm{~g}(\mathrm{~d})$ basis set. Input geometries were

constructed from modified crystallographic coordinates. The geometry-optimized $x y z$ coordinates for all structures are provided in the supporting information (Tables S1 and S2). The calculations indicate that, in the gas phase, the Gibbs free energy of the symmetric 'succinimidine' tautomer is $\sim 1.9 \mathrm{kcal} \mathrm{mol}^{-1}$ more stable than the asymmetric form observed crystallographically. The energy difference is small enough to allow for the network of hydrogen bonds in the crystal structure to dictate which tautomer of the compound is observed in the solid state. This packing-influenced tautomerization also aligns with previous tautomer-based studies that utilized variable-temperature crystallography and thermal evolution to better understand the tautomer ratios in keto-amine/iminoenol systems (Godsi et al., 2004). To examine which tautomer is preferred in solution, we examined a solution of $\mathbf{1}$ in DMSO- $d_{6}$ by ${ }^{1} \mathrm{H}$ NMR spectroscopy. The main signal observed is a singlet at 2.46 ppm assignable to the $\mathrm{CH}_{2}$ protons, consistent with the symmetric 'succinimidine' tautomer. This provides evidence that in solution, the imidine structure, as historically drawn in textbooks (March, 1992), dominates, yet in the solid state, the asymmetric tautomer is prevalent. Additionally, the singlet at 7.37 ppm likely indicates rapid exchange between all three of the NH protons. For reference, the ${ }^{1} \mathrm{H}$ NMR spectrum of succinimide in $\mathrm{CDCl}_{3}-d_{1}$

Figure 6

Dotted lines are used to indicate hydrogen-bonding interactions. The figure depicts hydrogen-bonding interactions between sheets, bridging pairs of these sheets.
consists of a singlet at 2.769 ppm (https://www.chemicalbook. com/SpectrumEN_123-56-8_1HNMR.htm).

### 3.2. Crystal packing

Unsurprisingly, the large number of hydrogen-bond donors and acceptors in the molecules examined here result in significant intermolecular hydrogen-bonding interactions throughout the crystal structures (Tables 3-7). In 1, 2, and 4, the hydrogen-bonding interactions result in oligomerization of the planar dimer units formed by the hydrophilic section of the molecules being paired together (Fig. 3). Each pair involves a double-hydrogen-bonded eight-membered ring reminiscent of the structural motifs seen for carboxylic acid dimers in the solid (Jasinski et al., 2009), solution (Kolbe et al., 1997), or gas phase (Emmeluth et al., 2003). The linking of these hydrogen-bonded dimers through further lateral hydrogen bonds creates long two-dimensional ribbons throughout the crystal lattice. These ribbons stack together to form the three-dimensional crystal structures. For both 1 and 4, there are no hydrogen-bonding interactions between ribbons either in the same plane or in between planes, as seen in Fig. 4. This pattern is broken with $\mathbf{2}$, where the methanol solvent molecule hydrogen bonds in between sheets. This additional hydrogenbonding interaction perpetuates throughout the packed crystal structure, making a series of interlaced sheets, as seen in Fig. 5. Compounds $\mathbf{1}$ and $\mathbf{2}$ contain a mismatch in the number of hydrogen-bond-donating and -accepting groups, leading to structures in which one of the potential hydrogenbond donors remains unsatisfied.

In the structure of $\mathbf{1} \cdot \mathrm{HCl}$, hydrophobic backbone and hydrophilic heteroatoms alternate in the plane, as seen in Fig. 1. Additionally, the solvent water molecule in $\mathbf{1} \cdot \mathrm{HCl}$ hydrogen bonds between sheets, bridging pairs of these sheets, as seen in Fig. 6. The major exception to the planar molecular sheets stabilized by a hydrogen-bond network is found in the crystal packing of $\mathbf{3}$. Compound $\mathbf{3}$ does not form discrete carboxylic acid-style dimers. Instead, each molecule of $\mathbf{3}$ has hydrogen-bonding interactions with four other molecules of $\mathbf{3}$ that form an interconnected three-dimensional lattice as the molecules stack perpendicular to each other, as seen in Fig. 7. The introduction of the three-dimensional hydrogen-bonding lattice is likely what aids in the crystallization of $\mathbf{3}$ from aqueous conditions.

## 4. Summary

Through careful analysis of solid-state and solution phase measurements of the historical imidines, the apparent experimental disagreement between whether their structures are asymmetric or symmetric tautomers has been resolved. The crystallographic data provide evidence for the solid-state asymmetric tautomer for both the five- and six-membered ring compounds, whereas solution phase NMR spectroscopy data strongly indicate a more symmetric form. The energetic differences between the symmetric and asymmetric forms were calculated to be sufficiently small to allow for tauto-

Figure 7

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

$T=100 \mathrm{~K}$

## Data collection

Bruker SMART APEXII diffractometer
Radiation source: sealed X-ray tube, Siemens, K FFCU 2K 90
Equatorially mounted graphite monochromator
Detector resolution: 7.9 pixels $\mathrm{mm}^{-1}$
$0.60 \backslash \omega$ and $0.6 \backslash \varphi$ scans
Absorption correction: multi-scan
(SADABS; Bruker, 2016)

Plate, colourless
$0.11 \times 0.11 \times 0.10 \mathrm{~mm}$
$T_{\text {min }}=0.844, T_{\text {max }}=0.901$
3673 measured reflections
892 independent reflections
833 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.019$
$\theta_{\text {max }}=72.2^{\circ}, \theta_{\text {min }}=7.1^{\circ}$
$h=-7 \rightarrow 7$
$k=-8 \rightarrow 8$
$l=-8 \rightarrow 8$

## Refinement

## Refinement on $F^{2}$

Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.034$
$w R\left(F^{2}\right)=0.092$
$S=1.09$
892 reflections
76 parameters
0 restraints
Primary atom site location: iterative

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

## Data collection

Bruker SMART APEXII diffractometer
Radiation source: sealed X-ray tube, Siemens, K FFCU 2K 90
Equatorially mounted graphite monochromator
Detector resolution: 7.9 pixels $\mathrm{mm}^{-1}$
$0.60 \backslash \omega$ and $0.6 \backslash \varphi$ scans
Absorption correction: multi-scan
(SADABS; Bruker, 2016)
$T_{\text {min }}=0.853, T_{\text {max }}=0.915$
7398 measured reflections
886 independent reflections
775 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.042$
$\theta_{\text {max }}=72.0^{\circ}, \theta_{\text {min }}=6.7^{\circ}$
$h=-9 \rightarrow 9$
$k=-9 \rightarrow 9$
$l=-9 \rightarrow 10$

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.033$
$w R\left(F^{2}\right)=0.089$
$S=1.03$
886 reflections
72 parameters
0 restraints
Hydrogen site location: mixed
H atoms treated by a mixture of independent and constrained refinement
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)+(0.0517 P)^{2}+0.1366 P\right]$ where $P=\left(F_{\mathrm{o}}^{2}+2 F_{\mathrm{c}}^{2}\right) / 3$
$(\Delta / \sigma)_{\text {max }}<0.001$
$\Delta \rho_{\max }=0.23 \mathrm{e} \AA^{-3}$
Primary atom site location: dual
$\Delta \rho_{\text {min }}=-0.18$ e $\AA^{-3}$

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

## 6-Imino-3,4,5,6-tetrahydropyridin-2-amine methanol monosolvate (2)

## Crystal data

$\mathrm{C}_{5} \mathrm{H}_{9} \mathrm{~N}_{3} \cdot \mathrm{CH}_{4} \mathrm{O}$
$M_{r}=143.19$
Monoclinic, $P 2_{1} / c$
$a=9.4887$ (9) Å
$b=14.5341$ (11) $\AA$
$c=12.2828(10) \AA$
$\beta=111.320(8)^{\circ}$
$V=1578.0(2) \AA^{3}$
$Z=8$

## Data collection

Bruker APEXII Quazar
diffractometer
$0.5^{\circ} \omega$ and $0.5^{\circ} \varphi$ scans
Absorption correction: multi-scan
(SADABS; Krause et al., 2015)
$T_{\min }=0.690, T_{\text {max }}=0.754$
26582 measured reflections

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.040$
$w R\left(F^{2}\right)=0.108$
$S=1.07$
3219 reflections
204 parameters
5 restraints
Primary atom site location: dual
$F(000)=624$
$D_{\mathrm{x}}=1.205 \mathrm{Mg} \mathrm{m}^{-3}$
$\mathrm{Cu} K \alpha$ radiation, $\lambda=1.54178 \AA$
Cell parameters from 9930 reflections
$\theta=4.9-74.4^{\circ}$
$\mu=0.70 \mathrm{~mm}^{-1}$
$T=100 \mathrm{~K}$
Block, yellow
$0.03 \times 0.02 \times 0.01 \mathrm{~mm}$

3219 independent reflections
2938 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.037$
$\theta_{\text {max }}=74.5^{\circ}, \theta_{\min }=4.9^{\circ}$
$h=-11 \rightarrow 9$
$k=-18 \rightarrow 18$
$l=-15 \rightarrow 15$

Hydrogen site location: mixed
H atoms treated by a mixture of independent and constrained refinement
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)+(0.052 P)^{2}+0.8148 P\right]$
where $P=\left(F_{0}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$
$(\Delta / \sigma)_{\text {max }}<0.001$
$\Delta \rho_{\text {max }}=0.35 \mathrm{e}_{\AA^{-3}}$
$\Delta \rho_{\text {min }}=-0.28$ e $\AA^{-3}$

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
