## Piperizinium hydrogen phosphite monohydrate

The title compound, $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{~N}_{2}{ }^{2+} \cdot \mathrm{HPO}_{3}{ }^{2-} \cdot \mathrm{H}_{2} \mathrm{O}$, contains doubly protonated piperizinium cations, hydrogen phosphite anions and water molecules. The component species have normal geometrical parameters and interact by way of $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds, resulting in [010] chains of alternating $\left[\mathrm{HPO}_{3}\right]^{2-}$ and $\mathrm{H}_{2} \mathrm{O}$ species, crosslinked by the organic moieties. A possible $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interaction is also present.

## Comment

The crystal structures of (protonated) amine hydrogen phosphites containing $\left[\mathrm{HPO}_{3}\right]^{2-}$ or $\left[\mathrm{H}_{2} \mathrm{PO}_{3}\right]^{-}$oxo-anions are of crystallochemical interest in terms of the interplay between the hydrogen bonds linking the cations, anions, and, if applicable, water molecules together (Averbuch-Pouchot, 1993a,b; Harrison, 2003a,b).

$\left[\mathrm{HPO}_{3}\right]^{2-} \mathrm{H}_{2} \mathrm{O}$
(I)

The asymmetric unit of the title compound, (I), consists of two half-molecule $\left\{\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{~N}\right\}$ fragments of $\left(\mathrm{C}_{4} \mathrm{H}_{12} \mathrm{~N}_{2}\right)^{2+}$ piperizinium cations, an $\left[\mathrm{HPO}_{3}\right]^{2-}$ hydrogen phosphite group and a water molecule. Inversion symmetry (Fig. 1) generates the two complete piperizinium cations, and the water O atom is disordered over two adjacent sites (see Experimental). The

Figure 1
View of (I) ( $50 \%$ displacement ellipsoids; H atoms are drawn as small spheres of arbitrary radius). The disordered $\mathrm{O} 4 b$ species is omitted. Symmetry codes: (i) $-x, 1-y,-z$; (ii) $1-x, 1-y,-z$.

Figure 2
Detail of a [010] hydrogen phosphite-water chain with the $\mathrm{H} \cdots \mathrm{O}$ components of the hydrogen bonds indicated by dashed lines (atom $\mathrm{O} 4 b$ not shown). Symmetry codes: (i) $x, y+1, z$; (ii) $x, y-1, z$.

Figure 3
Unit-cell packing in (I) projected onto (010). The H $\cdots$ O components of the hydrogen bonds are indicated by dashed lines. O4b and all C-H H atoms are omitted for clarity.
hydrogen phosphite group shows its usual (Harrison, 2003a) pseudo-pyramidal geometry [mean $d(\mathrm{P}-\mathrm{O})=1.521$ (2) $\AA$; mean $\left.\theta(\mathrm{O}-\mathrm{P}-\mathrm{O})=112.48(9)^{\circ}\right]$ and the organic species adopt typical chair conformations.

As well as electrostatic forces, the component species in (I) interact by means of $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds (Table 2), and possibly a $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ interaction (see below). Infinite chains of alternating $\left[\mathrm{HPO}_{3}\right]^{2-}$ and $\mathrm{H}_{2} \mathrm{O}$ moieties are formed (Fig. 2) along [010] as a result of the water-to-phosphite $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds, with the repeating units generated by translation symmetry. The resulting P1..P1 $1^{\text {ii }}$ (Fig. 2; see Table 2 for symmetry code) separation of 6.5706 (7) $\AA$ is naturally much larger than the typical P...P separations (4.7-4.9 Å) seen when $\left[\mathrm{H}_{2} \mathrm{PO}_{3}\right]^{-}$ dihydrogen phosphite units link together by way of $\mathrm{P}-\mathrm{O}-$ $\mathrm{H} \cdots \mathrm{O}-\mathrm{P}$ interactions without an intervening water molecule (Averbuch-Pouchot, 1993a, Harrison, 2003a).

The piperizinium cations crosslink the $[010]\left[\mathrm{HPO}_{3}\right]^{2-}-\mathrm{H}_{2} \mathrm{O}$ chains by way of the $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds (Table 2), with all four bonds close to linear [mean $\theta(\mathrm{N}-\mathrm{H} \cdots \mathrm{O})=168^{\circ}$ ]. A short $\mathrm{C} 1-\mathrm{H} 5 \cdots \mathrm{O} 4 a^{\text {iv }}$ (Table 2) interaction was identified in a PLATON (Spek, 2003) analysis of (I). If it is not merely a packing artefact, it may provide some additional coherence
between the piperizinium cations and the water component of the $\left[\mathrm{HPO}_{3}\right]^{2-}-\mathrm{H}_{2} \mathrm{O}[010]$ chains, although its role, if any, in the disordering of the water molecule O 4 atom is not obvious.

## Experimental

$\mathrm{H}_{3} \mathrm{PO}_{3}(0.82 \mathrm{~g} ; 1 \mathrm{mmol})$ and piperizine hexahydrate $(1.92 \mathrm{~g}$; 0.01 mmol ) were dissolved in 10 ml deionized water, resulting in a clear solution. Block-shaped crystals of (I) grew as the water evaporated over several days.

The water O atom was modelled as being disordered over two adjacent sites with isotropic displacement factors $[d(\mathrm{O} 4 a \cdots \mathrm{O} 4 b)=$ 0.638 (5) $\AA$; fractional site occupancies $=0.563$ (14) and 0.437 (14) for O4a and O4b, respectively, with their sum constrained to unity]. The present data did not reveal H -atom sites that could be unambiguously associated with either O4a or $\mathrm{O} 4 b$; instead, two distinct features in
the difference map provided H -atom sites that were reasonable for both $\mathrm{O} 4 a$ and $\mathrm{O} 4 b$ (see Table 2). These $\mathrm{O}-\mathrm{H}$ H atoms were refined by riding on $\mathrm{O} 4 a$ in their as-found positions. The $\mathrm{N}-\mathrm{H} \mathrm{H}$ atoms were found in difference maps and refined by riding in their idealized positions $[d(\mathrm{~N}-\mathrm{H})=0.90 \AA$ ]. The H atoms bonded to C and P were placed in calculated positions $[d(\mathrm{C}-\mathrm{H})=0.97 \AA ; d(\mathrm{P}-\mathrm{H})=1.32 \AA]$ and refined by riding. For all H atoms, the constraint $U_{\text {iso }}(\mathrm{H})=$ $1.2 U_{\text {eq }}$ (carrier atom) was applied.

Data collection: SMART (Bruker, 1999); cell refinement: SAINT (Bruker, 1999); data reduction: SAINT; program(s) used to solve structure: SHELXS97 (Sheldrick, 1997); program(s) used to refine structure: SHELXL97; molecular graphics: ORTEP-3 (Farrugia,
1997); software used to prepare material for publication: SHELXL97.

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving 1.s. planes.

Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors $(\mathrm{gt})$ etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
