Received 19 January 2009; accepted 7 February 2009

Key indicators: single-crystal X-ray study;  $T = 291$  K; mean  $\sigma(\text{C}-\text{C}) = 0.007$  Å;  $R$  factor = 0.061;  $wR$  factor = 0.135; data-to-parameter ratio = 12.5.

In the title compound,  $[\text{Zn}(\text{C}_{14}\text{H}_{11}\text{O}_2)_2(\text{C}_{10}\text{H}_8\text{N}_2)(\text{H}_2\text{O})_2]_n$ , the  $\text{Zn}^{\text{II}}$  ion lies on a crystallographic inversion center and is in a slightly distorted octahedral coordination environment. 4,4'-Bipyridine ligands act as bridging ligands, connecting  $\text{Zn}^{\text{II}}$  ions into a chain along the  $b$ -axis direction. In the crystal structure, these chains are linked by intermolecular  $\text{O}-\text{H}\cdots\text{O}$  hydrogen bonds to form a two-dimensional network parallel to the  $ab$  plane.

**S1. Comment**

During the past decade, the design of new metal-organic supramolecular solids has attracted attention in the fields of coordination chemistry and crystal engineering, for the sake of developing desired crystalline materials with potential functionality (Moulton & Zaworotko, 2001; Janiak, 2003). Furthermore, it has been realised that weak noncovalent interactions such as hydrogen bonds, aromatic stacking, and van der Waals forces (Hosseini, 2005; Nishio, 2004) are crucial in the direction of such crystalline architectures. Hitherto, a variety of organic connectors containing pyridyl and/or carboxylate groups (Brammer, 2004) have been widely used to construct metal-organic supramolecular frameworks. Herein we report the crystal structure of the title compound (1).

The asymmetric unit of (1) is illustrated in Fig. 1. The structure of (1) is a one-dimensional chain (Fig. 2), in which the  $Zn^{II}$  ions are coordinated by two O atoms from two monodentate carboxylate groups of two bis(diphenylacetato) ligands, two N atoms of two bridging 4,4'-bipyridine ligands and two O atoms from two water molecules. The  $Zn^{II}$  ion is in a slightly distorted octahedral coordination environment. In the crystal structure, these one-dimensional chains are linked via intermolecular O—H $\cdots$ O hydrogen bonds to form a two-dimensional network.

**S2. Experimental**

Solid  $ZnCl_2$  (136 mg, 1 mmol), 4,4'-bipyridine (1 mmol, 0.156 g) and diphenylacetic acid (212 mg, 1 mmol) in water (8 ml) was placed in a Teflon-lined stainless-steel Parr bomb that was heated at 433 K for 48 h. Colorless block crystals were collected after the bomb was subsequently allowed to cool to room temperature.

**S3. Refinement**

The C-bound H atoms were placed to the bonded parent atoms in geometrically idealized positions (C—H = 0.93, and 0.98 Å) and refined as riding atoms, with  $U_{iso}(H) = 1.2U_{eq}(C)$ . The O-bound H atoms were located in difference Fourier maps and refined as riding in their as-found positions but with O—H = 0.96 Å and with  $U_{iso}(H) = 1.5U_{eq}(C)$ .

**Figure 1**

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
