4-(3-Ammoniopropyl)morpholin-4-ium tetrachloridozincate(II)

Meher El Glaoui,[a] Erwann Jeanneau,[b] Mohamed Rzaigui[a] and Cherif Ben Nasr[a]*

[a]Laboratoire de Chimie des Matériaux, Faculté des Sciences de Bizerte, 7021 Zarzouna, Tunisia, and [b]Universtié Lyon1, Centre de Diffractométrie Henri Longchambon, 43 Boulevard du 11 Novembre 1918, 69622 Villeurbanne Cedex, France
Correspondence e-mail: cherif_bennasr@yahoo.fr

Received 26 January 2009; accepted 6 February 2009

Key indicators: single-crystal X-ray study; T = 293 K; mean σ(C–C) = 0.002 Å; R factor = 0.019; wR factor = 0.020; data-to-parameter ratio = 19.7.

In the title compound, $(C_7H_{18}N_2O)[ZnCl_4]$, the Zn^{II} ion is coordinated by four Cl atoms in a close to tetrahedral geometry. The crystal packing exhibits C—H···Cl, N—H···Cl and N—H···O hydrogen bonds.

4-(3-Ammoniopropyl)morpholin-4-ium tetrachloridozincate(II)

Meher El Glaoui, Erwann Jeanneau, Mohamed Rzaigui and Cherif Ben Nasr

S1. Comment

Hybrid compounds have many practical and potential applications in various field (Tao *et al.*, 2003; Bringley and Rajeswaran, 2006). In these materials, the crystal packing is ensured by hydrogen bonds and coulombic interactions (Brammer *et al.*, 2002). Here we report the crystal structure of the title compound, 4-(3-ammoniopropyl)morpholin-4-ium tetrachlorozincate (II) (Fig. 1).

As shown in Fig. 1, to ensure charge balance, the organic species is double protonated at N1 and N2 nitrogen atoms. The structure consists essentially of an 4-(3-ammoniopropyl)morpholin-4-ium and $[ZnCl_4]^{2-}$ anion which are held together by N—H···Cl and C—H···Cl hydrogen bonds so as to build layers developing parallel to (a, c) planes (Fig. 2). These layers, situated at $y = {}^1/_4$ and $y = {}^3/_4$, are themselves interconnected by a set of N2—H···Cl hydrogen bonds (Table 1), alternating with layers, to form a three dimensional infinite network (Fig. 3). The Zn (II) ion is in tetrahedral coordination environment composed of four chloride ions. Each $ZnCl4^{2-}$ anion is connected to its neighbors organic cations, which are associated *via* N—H···O hydrogen bonds, by N—H···Cl and C—H···Cl interactions involving four chlorine atoms (Table 1). The Cl1 and Cl4 are simple acceptors, the Cl3 is double acceptor and the Cl2 is triple acceptor of hydrogen bonds. The (N)—H···Cl distances, varying between 2.42 and 2.54 Å, are smaller than the sum of the Van der Walls radii of the chlorine and hydrogen atoms [*r*(Cl) + r(H) = 2.81 Å]. Consequently, these values correspond well to strong hydrogen bonds.

However, it is worth noticing that the Zn—Cl bond lengths and Cl—Zn—Cl bond angles in the $[ZnCl_4]^{2-}$ anion are not equal to one another but vary with the environment around the Cl atoms(Valkonen *et al.*, 2006). In the title compound, the Zn—Cl bond lengths vary between 2.2486 (4) and 2.2950 (4) Å. The Cl—Zn—Cl bond angles range from 104.32 (1) to 114.43 (2) °. These values indicate that the anionic $[ZnCl_4]^{2-}$ tetrahedron is slightly distorted (Guo *et al.*, 2007).

S2. Experimental

$ZnCl_2$, aqueous 1*M* HCl solution and 3-Morpholinopropylamine in a 1:2:1 molar ratio were mixed and dissolved in sufficient ethanol. Single crystals suitable for X-ray diffraction were prepared by evaporation of a solution of the title compound in ethanol at room temperature after a few days.

S3. Refinement

The H atoms were all located in a difference map, but those attached to carbon atoms were repositioned geometrically. The H atoms were initially refined with soft restraints on the bond lengths and angles to regularize their geometry (C—H in the range 0.93–0.98, N—H in the range 0.86–0.89 and O—H = 0.82 Å) and U_{iso}(H) (in the range 1.2–1.5 times U_{eq} of the parent atom), after which the positions were refined with riding constraints.
