Received 21 February 2009; accepted 24 February 2009
Key indicators: single-crystal X-ray study; $T=150 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.008 \AA$; $R$ factor $=0.060 ; w R$ factor $=0.166$; data-to-parameter ratio $=18.6$.

The title compound, $\mathrm{C}_{11} \mathrm{H}_{15} \mathrm{BrN}_{2} \mathrm{O}_{2}$, contains an amide group which is close to coplanar with the adjacent pyridine ring, the dihedral angle between the planes being $9.0(5)^{\circ}$. The molecular packing reveals a mutual hydrogen-bond interaction between centrosymmetrically related hydroxyl O atoms. Further hydrogen bonding involving $\mathrm{O}-\mathrm{H} \cdots \mathrm{Br}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{Br}$ interactions also appears to consolidate the packing.

## rac- $N$-\{6-[Bromo(hydroxy)methyl]-2-pyridyl\}pivalamide

James C. Knight, Fawaz A. Saad, Angelo J. Amoroso, Benson M. Kariuki and Simon J. Coles

## S1. Comment

During research focused on new synthetic routes towards novel poly-pyridyl co-ordination compounds, we observed an unexpected by-product in one of our syntheses. As we attempted to prepare $N$-(6-(bromomethyl)pyridin-2-yl)pivalamide (1) from $N$-(6-methylpyridin-2-yl)pivalamide and $N$-bromosuccinimide (NBS) in the presence of azobisisobutyronitrile (AIBN) (Harata et al., 1995), the title compound (2) was isolated in low yield (Fig. 3).

We postulate that during the free-radical driven mono-bromination reaction (Scheme 2), a small quantity of $N$-(6-(di-bromomethyl)pyridin-2-yl)pivalamide is generated. The formation of $\mathbf{2}$ would proceed via an $\mathrm{S}_{\mathrm{N}} 1$ reaction involving water, arising as a minor contaminant within the solvent. Subsequent elimination of HBr would lead to the formation of the corresponding aldehyde, however, we have isolated this intermediate prior to HBr elimination.

The formation of the stereogenic centre ( C 1 ) from achiral starting materials without any optically active agent has naturally led to a racemic compound. The geometry surrounding the C 1 atom is a distorted tetrahedron, which supports the $s p^{3}$-hybridization of this carbon, and the comparatively long C1-O1 bond (1.440(8) $\AA$ ) confirms the presence of an alcohol rather than a ketone. Additionally, while no hydroxyl proton was observed in the ${ }^{1} \mathrm{H} N \mathrm{NR}$, the spectrum revealed a diagnostic singlet at a considerable downfield shift of 6.40 p.p.m. which, according to the ${ }^{1} \mathrm{H}$ NMR prediction software (CHEMDRAW Ultra 8.0; Cambridge Soft 2001), is indicative of a proton (H1) in an $\alpha$-position to a hydroxyl group and a bromine atom. The single-crystal infrared spectrum of this compound also features just a single band in the carbonyl region ( $1694.0 \mathrm{~cm}^{-1}$ ) attributable to the amide carbonyl stretch. The bond lengths and angles of the title compound are in good agreement with the expected values (Goswami et al., 2005).
The mutual H -bond interaction between hydroxyl oxygen atoms O 1 and $\mathrm{O} 1^{\mathrm{i}}$ (Fig. 2) results in a short $\mathrm{H} \cdots \mathrm{H}$ distance $(1.87 \AA)$ which is indicative of some disorder between the hydroxyl groups. Attempts at modeling this disorder have given unsatisfactory results. See Table 1 for details of other H-bond interactions which support the crystal packing (Fig. $3)$.

## S2. Experimental

$N$-(6-methylpyridin-2-yl)pivalamide ( $40 \mathrm{~g}, 0.207 \mathrm{~mol}$ ), NBS ( $56 \mathrm{~g}, 0.315 \mathrm{~mol}$ ), and a catalytic amount of AIBN were dissolved in carbon tetrachloride ( 400 ml ). The reaction mixture was heated at reflux for 13 h . The resulting crude brown oil was purified via column chromatography (hexane:ethyl acetate (95:5)). Recrystallization from hexane afforded crystals (yield 1.7\%) suitable for X-ray diffraction. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz} ; \mathrm{CDCl}_{3}$ ): $7.94(s, 1 \mathrm{H}, \mathrm{H} 2), 7.92(d, 1 \mathrm{H}, J=7.87$ Hz , py-H5), $7.70(t, 1 \mathrm{H}, J=7.89 \mathrm{~Hz}$, py-H4), $7.37(d, 1 \mathrm{H}, J=7.60 \mathrm{~Hz}$, py-H3), $6.40(s, 1 \mathrm{H}, \mathrm{H} 1), 1.27(s, 9 \mathrm{H}, \mathrm{H} 9-11)$. IR ( KBr disk): $1694.0 \mathrm{~cm}^{-1}\left(-\mathrm{C}=\mathrm{O}\right.$ ). HRMS (EI) $\mathrm{m} / \mathrm{z}$ : calc. for $\mathrm{C}_{11} \mathrm{H}_{15} \mathrm{BrN}_{2} \mathrm{O} 270.0368$, found 270.0373.

## S3. Refinement

H atoms attached to $\mathrm{C}, \mathrm{N}$ and O atoms were placed in calculated positions and subsequently treated as riding with $\mathrm{C}-\mathrm{H}$ distances of $0.95-1.00 \AA$, an $\mathrm{N}-\mathrm{H}$ distance of $0.88 \AA$, and an $\mathrm{O}-\mathrm{H}$ distance of $0.84 \AA$. The $U_{\mathrm{iso}}(\mathrm{H})$ was set to be 1.5 eeq of the carrier atom for hydroxyl and methyl H atoms, and $U_{\text {iso }}(\mathrm{H})=1.2 U \mathrm{eq}(\mathrm{C})$ for all other H atoms. The deepest hole in electron density $\left(-0.99 \mathrm{e}^{-3}\right)$ is located at the distance of $0.36 \AA$ from O1.

## Figure 1

Molecular structure of the title compound, showing the atom numbering. Displacement ellipsoids are drawn at the $50 \%$ probablility level. H atoms are represented by circles of arbitrary size.

## Figure 2

A view showing the mutual H -bond interaction between centrosymmetrically related hydroxyl oxygen atoms O 1 and $\mathrm{Ol}^{\mathrm{i}}$. A short $\mathrm{H} \cdots \mathrm{H}$ distance is suggestive of unresolved synchronized disorder between these groups. The hydrogen atom is also involved in H-bonding with a bromine acceptor atom located on a different molecule. [symmetry code (i): $1-x, y$ 1/2, 3/2-z.]

Figure 3
A view of the molecular packing. H-bonding interactions are indicated by a dashed line. Displacement ellipsoids are drawn at the $50 \%$ probablility level. H atoms are represented by circles of arbitrary size.

Extinction coefficient: 0.011 (2)

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors $(\mathrm{gt})$ etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
