Correspondence e-mail: luger@chemie.fu-berlin.de

Received 13 March 2009; accepted 16 March 2009
Key indicators: single-crystal X-ray study; $T=298 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.002 \AA$; $R$ factor $=0.060 ; w R$ factor $=0.190 ;$ data-to-parameter ratio $=29.3$.

The title compound, $\mathrm{C}_{18} \mathrm{H}_{17} \mathrm{NO}$, was isolated from the seeds of Clausena lansium (wampee) (Rutaceae). The X-ray crystal structure analysis confirmed its chemical identity and revealed that it is solvent-free, in contrast to the previously reported monohydrate [Huang, Ou \& Tang (2006). Acta Cryst. E62, o1987-o1988]. The molecular structures are practically identical but the molecules pack differently. In contrast to the monohydrate in which the water molecule generates two hydrogen bonds, no such intermolecular contacts are present in the title compound. The dihedral angle between the cinnamamide and the styryl group is $53.1(1)^{\circ}$.

# N -Methyl- N -styrylcinnamamide (lansamide) from Clausena lansium in Vietnam Peter Luger, Manuela Weber, Tran Dinh Thang, Hoang Van Luu and Nguyen Xuan Dung 

## S1. Comment

The title compound $N$-methyl- $N$-styrylcinnamamide [ $N$-methyl-3-phenyl- $N$-(2-phenylethenyl)-2-propenamide] (I) was isolated from the seeds of Clausena lansium (wampee) (Rutaceae). The leaves have been used as a folk medicine for the treatment of coughs, asthma and gastrointestinal diseases. The fruit is used for digestive disorders and the seeds are used for gastro-intestinal diseases such as acute and chronic gastrointestinal, ulcers, etc. (Loi, 2001).
The X-ray structure of the monohydrate of (I) was reported recently (Huang et al., 2006) wherein it was reported that "the corresponding anhydrous compound is a pale-yellow liquid at room temperature". Surprisingly, we could grow paleyellow crystals of the water-free form from n-hexane and its X-ray structure, which is subject of this study, was carried out to confirm its chemical identity.
The molecular structure of (I) is shown in Fig. 1 and its superposition with the molecule found in the monohydrate structure is shown in Fig. 2. Both structures are practically identical with a small difference of $10^{\circ}$ in the rotation of the styryl phenyl ring along the bond $\mathrm{C} 11-\mathrm{C} 12$ : torsion angle $\mathrm{C} 10-\mathrm{C} 11-\mathrm{C} 12-\mathrm{C} 13=148.7$ (1) ${ }^{\circ}$ for (I) and $139.0(3)^{\circ}$ for the monohydrate. Bond lengths and angles, which are all in the expected ranges, have an average difference of $0.007 \AA$ and $0.4^{\circ}$ between (I) and the monohydrate.
The triclinic lattice of (I) is illustrated in Fig. 3. In contrast to the monohydrate where the water molecule generates two hydrogen bonds in a body centered tetragonal lattice, no such intermolecular contacts are present in (I). Nevertheless, the packing in the triclinic lattice shows some characteristic features. The molecule consists of two planar fragments, the cinnamamide and the styryl group, forming an interplanar angle of $53.1(1)^{\circ}$. In molecular pairs related by the inversion centre at $(1 / 2,1 / 2,1)$, the cinnamamide fragments are aligned in parallel planes with a shortest contact distance of C atoms of adjacent planes being $\mathrm{C} 1 \cdots \mathrm{C} 8=3.664$ (3) $\AA$. Such an arrangement of cinnamamide groups was also observed in the monohydrate structure. The styryl groups also form co-planar planes for molecules related by the inversion centre at $(1 / 2,1 / 2,1 / 2)$, the shortest distance between C atoms of adjacent planes is C11 $\cdots \mathrm{C} 17=3.730$ (3) $\AA$ (see dashed lines in Fig. 3). This arrangement of styryl groups was not observed in the monohydrate structure.

## S2. Experimental

The dried seeds of C . lansium ( $3,0 \mathrm{~kg}$ ) were powdered and extracted with MeOH at room temperature, and the combined extracts were concentrated under reduced pressure to give a deep-brown syrup ( 160 g ). This was partitioned between $\mathrm{H}_{2} \mathrm{O}$ and n -hexane. The n -hexane-soluble residue ( 85 g ) was chromatographed over a silica gel column, which developed by gradient elution with n-hexane and increasing concentrations of $\mathrm{Me}_{2} \mathrm{CO}$ to afford forty fractions. Fractions were combined on their TLC. After standing for several day, fractions $9-11$ recrystallized from n-hexane to afford pale-yellow lansamide ( 2554 mg ).

## S3. Refinement

Carbon-bound H -atoms were placed in calculated positions ( $\mathrm{C}-\mathrm{H} 0.93$ to $0.96 \AA$ ) and were included in the refinement in the riding model approximation, with $U(\mathrm{H})$ set to 1.2 to $1.5 U(\mathrm{C})$.

Figure 1
Molecular structure of (I) with atom numbering scheme, displacement ellipsoids are shown at the $50 \%$ probability level.

Figure 2
Superposition of (I) (red) and the monohydrate (blue) forms of lansamide.

Figure 3
Stereo drawing of packing in (I) shown in projection onto the yz-plane. The $\mathrm{C} 1 \cdots \mathrm{C} 8$ and $\mathrm{C} 11 \cdots \mathrm{C} 17$ contacts are shown by dashed lines.

where $P=\left(F_{0}^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$
$(\Delta / \sigma)_{\text {max }}<0.001$
$\Delta \rho_{\text {max }}=0.36$ e $\AA^{-3}$
$\Delta \rho_{\min }=-0.14 \mathrm{e}^{-3}$

## Special details

Experimental. Bruker AXS APEX CCD area detector on Huber four circle diffractometer is used
Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving 1.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors $(\mathrm{gt})$ etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
