In the paper by Rohlicek et al. [Acta Cryst. (2009), E65, o1325-o1326], one H atom was placed incorrectly.

Following our powder-diffraction study of capecitabine (Rohlicek et al., 2009), Malińska et al. (2014) published the crystal structure of the same molecule based on single-crystal data. Although they modelled the wrong enantiomer [as was pointed out by Kratochvil et al. (2016)], the structures are very similar after inverting the single-crystal structure, including

Figure 1
Overlay of the capecitabine molecular structures arising from powder diffraction (blue) and from single-crystal diffraction data (red). Only nonH atoms are shown for clarity.

(a)
(b)

Figure 2
Schemes for the tautomeric forms of capecitabine (a) assumed in the powder-diffraction study and (b) established in the single-crystal study of Malinska et al. (2014).
the disordered part of the molecule (Fig. 1). Since singlecrystal diffraction is more sensitive to H atoms than powder diffraction, Malinska et al. (2014) were able to locate the H atoms directly. This indicated a different tautomeric form of capecitabine to that assumed in our study, and as they pointed out, we had therefore placed one H atom wrongly.

In our defence, in the powder study, we placed the H atoms geometrically according to a reasonable chemical structure for capecitabine, which shows the tautomeric H atom attached to the N atom of the carbamate group and the plausible formation of an intermolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond. As shown by Malińska et al. (2014), the H atom is actually located on the N atom of the pyrimidine ring (Fig. 2), thereby forming an intramolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ link.

With respect to the fact that structure solution from powder diffraction data is based on the proposed molecular structure, readers should beware of the incorrectly placed H atom in Rohlicek et al. (2009) and they should be also beware of the wrong enantiomer in a single-crystal study of Malińska et al. (2014).

Received 3 April 2009; accepted 12 May 2009
Key indicators: powder synchrotron study; $T=293 \mathrm{~K} ;$ mean $\sigma(\mathrm{C}-\mathrm{C})=0.004 \AA$; disorder in main residue; $R$ factor $=0.055 ; w R$ factor $=0.074$; data-to-parameter ratio $=5.5$.

In the title compound [systematic name 5-deoxy-5-fluoro- N (pentyloxycarbonyl)cytidine], $\mathrm{C}_{15} \mathrm{H}_{22} \mathrm{FN}_{3} \mathrm{O}_{6}$, the pentyl chain is disordered over two positions with refined occupancies of 0.53 (5) and 0.47 (5). The furan ring assumes an envelope conformation. In the crystal, intermolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds link the molecules into chains propagating along the $b$ axis. The crystal packing exhibits electrostatic interactions between the 5 -fluoropyrimidin- $2(1 H)$-one fragments of neighbouring molecules as indicated by short $\mathrm{O} \cdots \mathrm{C}$ [2.875 (3) and 2.961 (3) A ] and F $\cdots C[2.886$ (3) A ] contacts.

# Capecitabine from X-ray powder synchrotron data 

Jan Rohlicek, Michal Husak, Ales Gavenda, Alexandr Jegorov, Bohumil Kratochvil and Andy Fitch

## S1. Comment

Capecitabine is the first FDA-approved oral chemotherapy for the treatment for some types of cancer, including advanced bowel cancer or breast cancer (Wagstaff et al., 2003; Jones et al., 2004). Capecitabine is 5-deoxy-5-fluoro- $N$-[(pentyl-oxy)carbonyl]-cytidine and in vivo is enzymatically converted to the active drug 5-fluorouracil. Crystal structure determination of capecitabine was not reported yet. In this paper we report crystal structure determination of the title compound from the powder diffraction data by using synchrotron radiation.
The asymmetric unit consists of one molecule of capecitabine (Fig 1). The crystal packing is stabilized by intermolecular interactions - electrostatic interactions proved by short $\mathrm{O} \cdots \mathrm{C}$ and $\mathrm{F} \cdots \mathrm{C}$ contacts (Table 1) and $\mathrm{N} — \mathrm{H} \cdots \mathrm{O}$ hydrogen bonds (Table 2).

## S2. Experimental

Samples of crystalline capecitabine were prepared by two methods, $a$ and $b$, respectively. Method $a$ : capecitabine ( 10 g ) was dissolved in $\mathrm{EtOH}(80 \mathrm{~g})$. The solution was concentrated under reduced pressure to a residual volume of 25 ml and kept under stirring overnight. The solid was filtered off and dried at room temperature furnishing capecitabine ( 6 g ). Method $b$ : capecitabine ( 18 g ) was dissolved in DCM $(200 \mathrm{~g})$ and the solution was evaporated to dryness under reduced pressure. The residue was taken up with toluene ( 400 g ) and about 150 g of solvent were distilled off. The solution was heated up to $50^{\circ} \mathrm{C}$ and then allowed to 3 spontaneously cool to $25^{\circ} \mathrm{C}$. After cooling to $0^{\circ} \mathrm{C}$, the solid was filtered off, washed with toluene and dried at $60^{\circ} \mathrm{C}$ under vacuum to constant weight furnishing capecitabine ( 16.5 g ).

## S3. Refinement

Both crystallization procedures lead to one polycrystalline form of capecitabine. It was confirmed by measuring on XRay powder diffractometer PANalytical Xpert Pro, $\mathrm{Cu} K \alpha$ radiation ( $\lambda=1.541874 \AA$ ). Attempts to determine the structure from these data were unsuccessful probably due to flexible molecule of capecitabine and low resolution of these data. The powder obtained by the first "a" procedure was used for structure determination. X-Ray diffraction data were collected on the high resolution diffractometer ID31 of the European Synchrotron Radiation Facility. The monochromatic wavelength was fixed at 0.79483 (4) $\AA$. Si (111) crystal multi-analyser combined with Si (111) monochromator was used (beam offset angle $\alpha=2^{\circ}$ ). A rotating 1-mm-diameter borosilicate glass capillary with capecitabine powder was used for the experiment. Data were measured from $1.002^{\circ} 2 \theta$ to $34.998^{\circ} 2 \theta$ at the room temperature, steps scans was set to $0.003^{\circ} 2 \theta$.

First 20 peaks were used by CRYSFIRE 2004 package (Shirley, 2000) to get a list of possible lattice parameters. The most probable result was selected $(a=5.21 \AA, b=9.52 \AA, c=34.79 \AA, \mathrm{~V}=1724 \AA 3$, FOM $(20)=330)$. If $15 \AA^{3}$ are used as an atomic volume for $\mathrm{C}, \mathrm{N}, \mathrm{O}$ and F and $5 \AA 3$ as a volume for hydrogen atom, the approximate molecular volume is
$485 \AA^{3}$. The found volume of $1724 \AA^{3}$ suggests that there are four molecules in the unit cell $(Z=4) . P 2_{l} 2_{l} 2_{l}$ space group was selected on the basic of peaks extinction and on the basic of agreement of the Le-bail fit. The structure was solved in program FOX (Favre-Nicolin \& Černý, 2002) using parallel tempering algorithm. The initial model was generated by AM1 computing method implemented in program MOPAC (Dewar et al., 1985). For the solution process hydrogen atoms were removed. This model was restrained with bonds and angles restraints, automatically generated by program FOX. The refinement was carried out in GSAS (Larson \& Von Dreele, 1994). Hydrogen atoms were added in positions based on geometry and structure was restrained by bonds and angles restraints. Five planar restraints for $s p^{2}$ hybridization were used (O20/C18/O19/N17, N17/C13/N14/C12, C13/C12/F16/C11, N14/C10/O15/N9 and C4/N9/C10/C11). Due to relatively high $U_{\text {iso }}$ thermal parameters of alkyl chain $(\mathrm{C} 21-\mathrm{C} 25)$ the structure was refined with two disordered chains (C21—C25 and C21a-C25a) with occupancy factors $0.53(5)$ and $0.47(5) . U_{\text {iso }}$ thermal parameters were constrained just for atoms in disordered chains by this way ( $\mathrm{C} 21 / \mathrm{C} 21 a, \mathrm{C} 22 / \mathrm{C} 22 a, \mathrm{C} 23 / \mathrm{C} 23 a, \mathrm{C} 24 / \mathrm{C} 24 a, \mathrm{C} 25 / \mathrm{C} 25 a$ ). At the final stage atomic coordinates of non-hydrogen atoms were refined to the final agreement factors: $R_{\mathrm{p}}=0.055$ and $R_{\mathrm{wp}}=0.0743$. The diffraction profiles and the differences between the measured and calculated profiles are shown in Fig. 2.

Figure 1
The molecular structure of capecitabine showing the atomic numbering. Displacement spheres are drawn at the 20\% probability level. Only major part of the disordered pentyl chain is shown.

## Figure 2

The final Rietveld plot showing the measured data (black thin-plus), calculated data (red line) and difference curve (blue line). Calculated positions of the reflections are shown by verical bars.
