Received 26 February 2009; accepted 23 July 2009

Key indicators: single-crystal X-ray study;  $T = 293\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.002\text{ \AA}$ ; H-atom completeness 92%; disorder in solvent or counterion;  $R$  factor = 0.043;  $wR$  factor = 0.127; data-to-parameter ratio = 21.6.

In the crystal structure of the title compound,  $[\text{Ni}(\text{N}_3)_2(\text{C}_{12}\text{H}_{12}\text{N}_2)_2]\cdot\text{H}_2\text{O}$ , the  $\text{Ni}^{II}$  atom is situated on a twofold axis and adopts a distorted octahedral geometry with the two 5,5'-dimethyl-2,2'-bipyridyl (dmbpy) and the two azide ligands in a *cis* arrangement. The water solvent molecule is disordered over two positions in a 1:1 ratio.

### S1. Comment

It is 121 years since Blau first reported (Blau, 1888) the synthesis of 2,2'-bipyridine (bpy) and described the first metal complexes of this important ligand. Since then bpy and its derivatives have been continuously and extensively used in several aspects of coordination chemistry (Constable, 1989; Constable & Steel, 1989; Juris *et al.*, 1988). However, up to now comparatively few X-ray crystal structures of ligand 5,5'-dimethyl-2,2'-bipyridyl (dmbpy) have been published (Albada *et al.*, 2004; Catalan *et al.*, 1995; Kooijman *et al.*, 2002). In this study, we report the synthesis and characterization of the new Ni(II) complex containing both dmbpy and azido ligands. Although 52 structures containing dmbpy with metals were found in the Cambridge Structural Database (CSD; Version 5.29, November 2008 update; Allen, 2002) there was only one case (CSD refcode POMFAZ; Hou, 2008) where en is present with both Ni<sup>II</sup> and 5,5'-dimethyl-2,2'-bipyridyl.

It is found that the Ni ion is coordinated by four nitrogen atoms from dmbpy and two azido nitrogen atoms, taking on a distorted octahedral geometry. The two bidentate ligands have a *cis* disposition around the metal ion, forming practically perpendicular planes [N2—Ni1—N2<sup>i</sup> 89.80 (7), N1—Ni1—N1<sup>i</sup> 176.19 (7) $^\circ$ ] (symmetry codes:  $i -x + 2, y, -z + 1/2$ ). The rigidity of these ligands causes the bond angles N1—Ni1—N2, 78.26 (5) $^\circ$  to deviate significantly from orthogonality. This causes the geometry about the Ni<sup>II</sup> ion to deviate slightly from that of an ideal octahedron. The Ni(1)—N(dmbpy) bond distances in a related complex [2.0897 (13) and 2.0882 (13) Å] (Urtiaga *et al.*, 1995) are almost the same as those found in the Ni(II) compound of [Ni<sup>II</sup>(bpy)<sub>2</sub>(N<sub>3</sub>)<sub>2</sub>] [2.067 (2)–2.114 (2) Å]. Good agreement is observed between the Ni(1)—N(azido) bond distance of 2.1053 (14) Å and those reported [2.094 (2) and 2.102 (3) Å] (Urtiaga *et al.*, 1995) for azido containing mononuclear nickel(II) complexes.

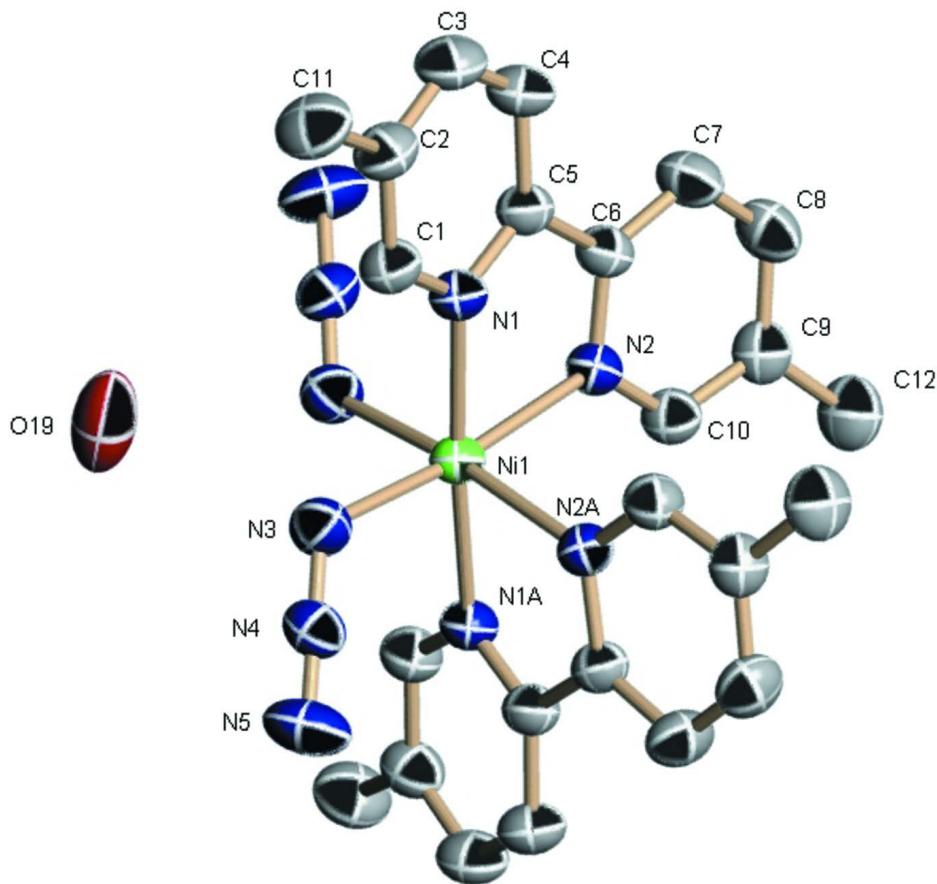

### S2. Experimental

All chemicals were obtained commercially and used without further purification. The compound was prepared by adding a warm solution of dmbpy (0.181 g, 1.0 mmol) in methanol (15 ml) to a warming aqueous solution (10 ml) of Ni(CH<sub>3</sub>COO)<sub>2</sub>·4H<sub>2</sub>O (0.123 g, 0.5 mmol). Afterward a solid of NaN<sub>3</sub> (0.065 g, 1.0 mmol) was added. The green solution was slowly evaporated at room temperature and after few days, green plate-shaped crystals of [Ni(dmbpy)<sub>2</sub>(N<sub>3</sub>)<sub>2</sub>]<sup>+</sup>·H<sub>2</sub>O formed. They were filtered off, washed with mother liquid and air-dried. Yield *ca* 89%. Elemental analysis (%) found (calculated): C 54.4 (54.6), H 4.9 (4.8), N 26.3 (26.5). The IR spectrum shows the band corresponding to the asymmetric stretch of the azido ion,  $\nu_{as}(N_3)$ , split at 2072 and 2024 cm<sup>-1</sup>. This indicates that the azido ligand is bonded asymmetrically by its two terminal N atoms.

### S3. Refinement

The water O atom is disordered which site occupancies of 0.5 and 0.5. All non-H atoms were refined anisotropically. H atoms in aromatic were placed in idealized positions and constrained to ride on their parent atoms, with C—H distances

of 0.96–1.01 Å [ $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ ]. H atoms of methyl groups of dmbpy were placed in calculated positions and refined with a riding model C—H = 0.96 Å.

**Figure 1**

A view of the title structure with the atom-numbering scheme and displacement ellipsoids drawn at the 30% probability level. H atoms have been omitted for clarity.

Extinction coefficient: 0.023 (3)

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
