Received 8 December 2009; accepted 9 December 2009

Key indicators: single-crystal X-ray study; $T=173 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.002 \AA$; $R$ factor $=0.032 ; w R$ factor $=0.088$; data-to-parameter ratio $=19.1$.

The title compound (systematic name: 2-mercaptoethanaminium chloride), $\mathrm{C}_{2} \mathrm{H}_{8} \mathrm{NS}^{+} \cdot \mathrm{Cl}^{-}$, the hydrochloride salt of cysteamine, in contrast to the previously reported triclinic polymorph [Kim et al. (2002). Polyhedron, 21, 225-228], crystallized in the monoclinic crystal system. In the crystal, the cysteaminium cations are linked to the chloride anions via one $\mathrm{S}-\mathrm{H} \cdots \mathrm{Cl}$ and three $\mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}$ hydrogen bonds. Twodimensional slab-like networks are formed, which are stacked in [100]. This arrangement is similar to that observed in the triclinic polymorph.

## A monoclinic polymorph of cysteamine hydrochloride

## Saeed Ahmad, Muhammad Ashraf Shaheen and Helen Stoeckli-Evans

## S1. Comment

The crystal structure of the triclinic polymorph, (I), of the title compound has been reported previously (Kim et al., 2002). Those crystals were prepared by recrystallization of cysteamine hydrochloride from hot alchohols, such as nbutanol, 2-propanol or n-propanol.
The stucture of the monoclinic polymorph, (II), is illustrated in Fig. 1, and the geometrical parameters are available in the Supplementary Information and the archived CIF. Here the crystalline sample received from the producers was used without further recrystallization. In contrast to (I), that crystallized with two independent molecules per asymmetric unit, polymorph (II) crystallized with one independent molecule per asymmetric unit. The conformation of the cation (i.e. torsion angle $\mathrm{S}-\mathrm{C}-\mathrm{C}-\mathrm{N}$ ) is similar in the two polymorphs: $61.49(16)^{\circ}$ in (II), and -60.28 and $60.65^{\circ}$ in (I).

In the crystal of (II) the cysteaminium cations are linked to the chloride anions, via one $\mathrm{S}-\mathrm{H} \cdots \mathrm{Cl}$ and three $\mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}$ hydrogen bonds (Table 1). Two-dimensional slab-like networks are formed, which stack in the [100] direction (Fig. 2). A similar hydrogen-bonded slab-like arrangement was also observed in the crystal structure of the triclinic polymorph (I), see Fig. 3.

## S2. Experimental

The sample used, supplied by Alfa Aesar (A Johnson Matthey Company) USA, consisted of colourless block-like crystals. A small piece of a large crystal was used for data collection.

## S3. Refinement

The H -atoms were all located in a difference electron-density map and were freely refined: $\mathrm{S}-\mathrm{H}=1.21(3) \AA ; \mathrm{N}-\mathrm{H}=$ 0.89 (3)-0.90 (3) $\AA ; \mathrm{C}-\mathrm{H}=0.95$ (2)-0.991 (17) $\AA$.

## Figure 1

A view of the molecular structure of the title compound, with the displacement ellipsoids drawn at the $50 \%$ probability level.

Figure 2
A view, along the $b$ axis, of the crystal packing of the title compound. The $\mathrm{S}-\mathrm{H} \cdots \mathrm{Cl}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}$ hydrogen bonds are shown as dotted cyan lines (see Table 1 for details).

Figure 3
A view, along the $a$ axis, of the crystal packing in the triclinic polymorph of the title compound (Kim et al., 2002). The S $-\mathrm{H} \cdots \mathrm{Cl}$ and $\mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}$ hydrogen bonds are shown as dotted cyan lines.

Extinction coefficient: 0.038 (9)

## Special details

Geometry. Bond distances, angles etc. have been calculated using the rounded fractional coordinates. All su's are estimated from the variances of the (full) variance-covariance matrix. The cell e.s.d.'s are taken into account in the estimation of distances, angles and torsion angles
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors $(\mathrm{gt})$ etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
