## [2,2'-(2,6,9,13-Tetraazatetradecane-1,14-diyl)diphenolato]iron(III) iodide

Gervas Assey, Ray J. Butcher,* Yilma Gultneh and Teshome Yisgedu<br>Department of Chemistry, Howard University, 525 College Street NW, Washington, DC 20059, USA<br>Correspondence e-mail: rbutcher99@yahoo.com

Received 11 May 2010; accepted 19 May 2010

Key indicators: single-crystal X-ray study; $T=200 \mathrm{~K}$; mean $\sigma(\mathrm{C}-\mathrm{C})=0.003 \AA$; $R$ factor $=0.033 ; w R$ factor $=0.066 ;$ data-to-parameter ratio $=36.3$.

The title $\mathrm{Fe}^{\mathrm{III}}$ complex, $\left[\mathrm{Fe}\left(\mathrm{C}_{22} \mathrm{H}_{32} \mathrm{~N}_{4} \mathrm{O}_{2}\right)\right] \mathrm{I}$, contains a sixcoordinate $\mathrm{FeN}_{4} \mathrm{O}_{2}$ cation in which the ligand is a reduced Schiff base resulting from the $\mathrm{NaBH}_{4}$ reduction of the condensation product between salicylaldehyde and 1,5,8,12tetraazadodecane. In spite of the increased flexibility of the saturated backbone of the ligand compared to the Schiff base from which it was synthesized, the complex adopts a cis$\mathrm{FeN}_{4} \mathrm{O}_{2}$ conformation for the phenolic O -atom donors, which contrasts with the trans conformation adopted by the analogous $\mathrm{ClO}_{4}{ }^{-}$salt [Yisgedu et al. (2009). J. Chem. Crystallogr. 39, 315-319]. In addition to extensive $\mathrm{N}-\mathrm{H} \cdots \mathrm{I}$ hydrogen bonding between the amine H atoms and the anion there is a weak $\mathrm{C}-\mathrm{H} \cdots \mathrm{I}$ interaction.

## S1. Comment

Metal complexes of linear hexadentate ligands have fascinated inorganic chemists since their first report in 1947 (Dwyer \& Lions, 1947). The first such report of an Fe complex of a linear $\mathrm{FeN}_{4} \mathrm{O}_{2}$ ligand derived from the Schiff base condensation of salicylaldehyde and triethylenetetraamine was in 1955 (Das Sarma \& Bailar, 1955). However, this interest lapsed for several years until the discovery that such complexes exhibited spin-crossover magnetic behavior (Sinn et al., 1978). Hexadentate linear $\mathrm{FeN}_{4} \mathrm{O}_{2}$ ligands derived from the Schiff base condensation of salicylaldehyde and linear tetramines can be characterized by the number of linking carbon atoms in the tetramine backbone (from 222 to 333). The structures of Fe complexes of Sal222 (Sinn et al., 1978; Hayami et al., 1997; Floquet et al., 2004; Dorbes et al., 2005; Bera et al., 2005; Nishida et al., 1987; Salmon et al., 1999; McPartlin et al., 1978; Maeda et al., 1991; Boinnard et al., 1994), Sal232 (Hayami et al., 1997), Sal323 (Hayami et al., 1997; Ito, et al., 1983), and Sal333 (Ito, et al., 1983) derivatives have been reported. When chelating to Fe , as the number of carbon atoms in the tetramine backbone increases from 6 to 9 , the conformation adopted by the ligand changes from a cis- $\mathrm{FeN}_{4} \mathrm{O}_{2}$ to a trans- $\mathrm{FeN}_{4} \mathrm{O}_{2}$ arrangement for the phenolic O donors. All structurally characterized Fe complexes with Sal222 have adopted the cis- $\mathrm{FeN}_{4} \mathrm{O}_{2}$ conformation while all those with either $\mathrm{Sal323}$ or $\mathrm{Sal333}$ have adopted the trans- $\mathrm{FeN}_{4} \mathrm{O}_{2}$ conformation. For Sal232, both conformations have been observed (Hayami et al., 1997). Further, it has been observed that, in addition to the usual reduction in metal ligand bond distances when going from high spin to low spin, the angles subtended at the Fe center reflect the magnetic properties of the compound (Hayami et al., 1997; Nishida et al., 1987) with low-spin compounds having such angles closer to $90^{\circ}$ and $180^{\circ}$.
Despite the interest shown in salicylaldimine complexes with $\mathrm{Fe}^{\text {III }}$ due to their interesting structural and magnetic properties, there have been very few structures reported on related complexes where the $\mathrm{C}=\mathrm{N}$ imine groups have been reduced to $\mathrm{C}-\mathrm{N}-\mathrm{H}$ amine groups (Harpstrite et al., 2003; Yisgedu et al., 2009). One of these is the perchlorate analog of the title compound (Harpstrite et al., 2003). As expected, due to increased flexibility of the saturated amine, compared to the more rigid Schiff base, and also the length of the carbon backbone, this compound has adopted a trans- $\mathrm{FeN}_{4} \mathrm{O}_{2}$ conformation. To further characterize such compounds and determine the conformation adopted the structure of an $\mathrm{Fe}^{\text {III }}$ complex of the iodide salt of reduced Sal323 is reported.
The title compound, [1,12-bis(2-hydroxybenzyl)-1,5,8,12-tetraazadodecane]iron(III) iodide, $\mathrm{C}_{22} \mathrm{H}_{32} \mathrm{FeIN}_{4} \mathrm{O}_{6}$, contains a six-coordinate $\mathrm{FeN}_{4} \mathrm{O}_{2}$ cation where the ligand $\left(\mathrm{H}_{2} \mathrm{~L}\right)$ is the $\mathrm{NaBH}_{4}$ reduction product of the Schiff base resulting from the condensation of salicylaldehyde and 1,4,8,12-tetraazadodecane. In marked contrast to the perchlorate salt with the same 323 backbone, the title compound has adopted a cis $\mathrm{FeN}_{4} \mathrm{O}_{2}$ conformation. It is of interest to compare the metrical parameters of both the cis and trans structures with the same central Schiff base core. In the title compound, the $\mathrm{Fe}-\mathrm{O}$ distances are shorter $[1.8898(13) / 1.8999(14) ~ \AA$ versus $1.9575(10) / 1.9142(10) \AA]$ while the $\mathrm{Fe}-\mathrm{N}$ distances are longer [ $\mathrm{Fe}-\mathrm{N}$ average of 2.202 (1) $\AA$ versus 2.162 (1) $\AA$ ]. Thus, even though they adopt different conformations, the bond distances and angles of both the perchlorate and iodide salts are more indicative of a high spin $\mathrm{Fe}^{\mathrm{III}}$ complex compared to
the similar reduced 232 complex (Yisgedu et al., 2009).
In addition to extensive hydrogen bonding between the amine H atoms and the anion there is a weak $\mathrm{C}-\mathrm{H} \cdots \mathrm{I}$ interaction (see table 1).

## S2. Experimental

Synthesis of ligand: The procedure for the synthesis of the ligand 1,12-bis(2-hydroxybenzyl)-1,4,8,12-tetraazaundecane $\left(\mathrm{H}_{2} \mathrm{~L}\right)$ (Yisgedu et al., 2009) is as follows: A solution of $6.1 \mathrm{~g}(50 \mathrm{mmol})$ of salicylaldehyde in 10 ml ethanol was added drop-wise to a solution of $4.0 \mathrm{~g}(25 \mathrm{mmol})$ of 1,5,8,12-tetraazadodecane in 15 ml of ethanol. A deep yellow solution was obtained and was stirred for half an hour. To this yellow solution was added a $\mathrm{NaBH}_{4}$ solution $(3.0 \mathrm{~g} \mathrm{NaBH} 4,0.4 \mathrm{~g}$ NaOH , and $40 \mathrm{ml}_{2} \mathrm{O}$ ). The volume of the solution was reduced to 20 ml and extracted with chloroform ( 3 x 40 ml ). The extracts were combined and dried with $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The $\mathrm{Na}_{2} \mathrm{SO}_{4}$ was filtered and the filtrate concentrated to a colorless thick oil ( $8.1 \mathrm{~g}, 87 \%$ ).
Synthesis of $\left[\mathrm{Fe}^{\mathrm{III} \mathrm{L}]\left(\mathrm{ClO}_{4}\right) \text { : The synthesis of the above complex (Yisgedu et al., 2009) is as follows: To } 0.85 \mathrm{~g}(2 \mathrm{mmol}) ~}\right.$ of $\mathrm{H}_{2} \mathrm{~L}$ dissolved in 10.0 ml of methanol was added $0.58 \mathrm{~g}(1 \mathrm{mmol})$ of $\mathrm{Fe}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{xH}_{2} \mathrm{O}$. The solution became violet and red-purple solids precipitated. This was stirred overnight, the solids filtered, washed with methanol and dried to give 1.65 g of red powder. Crystallization was effected by evaporation of a DMF solution of the complex (yield, $0.96 \mathrm{~g}, 67 \%$ ).
Synthesis of $\left[\mathrm{C}_{22} \mathrm{H}_{32} \mathrm{FeN}_{4} \mathrm{O}_{2}\right]$ I complex: A solution of $0.05 \mathrm{~g}(0.088 \mathrm{mmol})$ of the complex $\left[\mathrm{Fe}^{\text {III }} \mathrm{L}\right] \mathrm{ClO}_{4}$ was mixed with a solution of $10 \% \mathrm{w} / \mathrm{v}$ aqueous solution of iodine and potassium iodide. 0.095 g of the aqueous solution of iodine/KI mixture in 5 ml methanol was mixed with the complex. The mixture was then stirred at room temperature for 24 hours. The solution was then evaporated, dissolved in DMF and filtered. The filtrate was layered with diethyl ether. After the diffusion process, brownish red crystals suitable for x-ray diffraction were obtained.

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor wR and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors $(\mathrm{gt})$ etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
