Correspondence e-mail: j.leciejewicz@ichtj.waw.pl

Received 11 April 2011; accepted 23 May 2011

Key indicators: single-crystal X-ray study; $T = 293$ K; mean $\sigma(\text{C}-\text{C}) = 0.002$ Å; R factor = 0.050; wR factor = 0.153; data-to-parameter ratio = 16.6.

In the structure of the title compound, $[\text{Li}(\text{C}_5\text{H}_4\text{N}_2\text{O}_2)(\text{NO}_3)]_n$, the Li^{I} ion is coordinated by two carboxylate O atoms donated by two ligands and two nitrate O atoms in a distorted tetrahedral geometry. Li^{I} ions, bridged by carboxylate O atoms, form molecular ribbons composed of dimeric units. Two nitrate O atoms link the ribbons into molecular layers parallel to (001). Hydrogen bonds are active between protonated heterocyclic N atoms as donors and carboxylate O atoms as acceptors. The layers are held together by van der Waals interactions.

Poly[(μ_2 -nitrate- κ^2 O:O')(μ_2 -pyrimidinium-2-carboxylato- κ^2 O:O')lithium(I)]**Wojciech Starosta and Janusz Leciejewicz****S1. Comment**

The structure of the title compound contains Li^I ions, each coordinated by two ligand carboxylato and two nitrate O atoms at the apices of a distorted trigonal pyramid. Its base is composed of coplanar carboxylato O1, nitrate O11 and O12^{II} atoms (Fig. 1). The Li^I ion is shifted by 0.0548 (2) Å above this plane. The carboxylato O2^{III} atom is at the apex of the pyramid. The Li—O bond distances fall in the range from 1.967 (3) to 2.019 (3) Å, commonly observed in the structures of Li complexes with carboxylate ligands (Table 1). The Li1—N1 bond distance of 2.467 (3) Å as too long was not allowed for in coordination of the Li ion. The pyrimidine ring is planar with r.m.s. of 0.0074 (2) Å. A hydrogen atom attached to the hetero-ring N2 atom, clearly visible on the Fourier map, maintains the charge balance. It links the N2 atom with the carboxylato O^I atom *via* a hydrogen bond of 2.5762 (17) Å. Bond distances and bond angles within the pyrimidine ring do not differ from those reported earlier in the structures of other metal complexes with the title ligand. The carboxylate group C7/O1/O2 makes with the ring a dihedral angle of 14.81 (2)°. Two Li^I ions, one coordinated by the carboxylato O1 atom, the other by the second carboxylato O2 atom of the same ligand form molecular ribbons composed of dimeric units (Fig. 2). The latter bridged by nitrate O11 and O12^{II} atoms give rise to molecular layers. While the nitrate O11 atom coordinates a Li^I ion in one ribbon plane, the O12 atom is bonded along the crystal *c* axis to a Li^I ion in an adjacent ribbon; the O11—N11—O12 bond angle is 120.44 (17)°. The third nitrate O13 atom is not involved in the coordination. The NO₃ group is planar with r.m.s. of 0.0023 (0) Å. It makes a dihedral angle of 28.8 (2)° with the ribbon plane. Since the bridging nitrate O12 atom is in a terminal position and it is bonded to the Li^I ion in the middle of an adjacent ribbon, a layer is formed. A sequence of open channels which propagate along crystal *a* direction form a layer parallel to the *ab* plane. The layers stacked along the crystal *c* direction are held together by van der Waals type interactions. A variety of polymeric molecular patterns have been recently observed in the structures of a number of divalent metal complexes with the title ligand, for example: Mn(II) (Rodríguez-Diéguez *et al.*, 2008; Zhang *et al.*, 2008a); Fe(II) and Co(II) (Rodríguez-Diéguez *et al.*, 2007; Zhao & Liu, 2010); Ca(II) (Zhang *et al.*, 2008a), complexes. Structures built of monomeric molecules have been also reported: in a Ag(I) complex by Kokunov & Gorbunova, (2007); in a Cu(II) complex by Soares-Varela *et al.*, (2008) and Zhang *et al.*, (2008a). The structures of two Co(II) complexes have been determined by Antolić *et al.*, (2000) and Zhang *et al.*, (2008b).

S2. Experimental

50 mL of an aqueous solution containing 1 mmol of pyrimidine-2-carbonitrile (Aldrich) and 1 mmol of lithium nitrate hydrate were boiled with constant stirring under reflux for 6 h. After cooling to room temperature 1 N HNO₃ was added dropwise until the pH reached 6. Then the solution was stirred for 3 h. After evaporation to dryness the residue was repeatedly dissolved in water and evaporated at room temperature until colourless single crystals of the title compound were deposited. The crystals were washed with cold methanol and dried in the air.

S3. Refinement

H atoms attached to pyridimidine-ring C atoms were placed at calculated positions with $C-H=0.93\text{ \AA}$ and treated as riding on the parent atoms with $U_{iso}(H)=1.2U_{eq}(C)$. The H atom attached to pyrimidine ring N2 atom has been found from the Fourier map and refined isotropically.

Figure 1

A fragment of the structure with the atom labeling scheme. Non-hydrogen atoms are shown as 50% ellipsoids. Symmetry code: (I) $-x + 3/2, y - 1/2, z$; (II) $-x + 1, -y + 1, -z + 1$; (III) $-x + 3/2, y + 1/2, z$.

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
