Correspondence e-mail: arquevedop@unal.edu.co

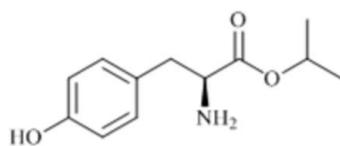

Received 4 October 2012; accepted 10 October 2012

Key indicators: single-crystal X-ray study;  $T = 233\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$ ;  $R$  factor = 0.036;  $wR$  factor = 0.099; data-to-parameter ratio = 8.3.

The title compound,  $\text{C}_{12}\text{H}_{17}\text{NO}_3$ , adopts a folded conformation with a  $\text{C}-\text{C}(\text{NH}_2)-\text{C}(=\text{O})-\text{O}$  torsion angle of  $-95.9(2)^\circ$ . In the crystal, molecules are linked by an  $\text{O}-\text{H}\cdots\text{N}$  hydrogen bond, forming helical chains along the  $b$ -axis direction. Weak  $\text{N}-\text{H}\cdots\text{O}$  and  $\text{C}-\text{H}\cdots\text{O}$  hydrogen bonds are observed between the chains.

## L-Tyrosine isopropyl ester

Nelson Nuñez-Dallos, Klaus Wurst and Rodolfo Quevedo

### S1. Comment

*L*-Tyrosine alkyl esters are used as prodrugs for *L*-tyrosine due to these esters are more lipophilic and absorbed faster than *L*-tyrosine. In addition, they are hydrolyzed under physiological conditions (Nicolaï *et al.*, 2011). The crystal structures for a number of tyrosine esters have been determined: methyl, ethyl (Nicolaï *et al.*, 2011) and *n*-butyl esters (Qian *et al.*, 2006). Previous computational and spectroscopic studies of *L*-tyrosine isopropyl ester have suggested that the macrocyclization process with formaldehyde can be explained by the formation of a template in solution through intermolecular hydrogen bonds between the amino and the phenolic hydroxyl groups on adjacent molecules of *L*-tyrosine derivatives (Quevedo & Moreno-Murillo, 2009; Nuñez-Dallos *et al.*, 2012). We report here for the first time the crystal structure of *L*-tyrosine isopropyl ester.

The molecular structure of the title compound is shown in Fig. 1. The molecule adopts a folded conformation called U-shaped or scorpion conformation, as evidenced in the C1—C2—C3—C4 torsion angle of 58.2 (3)°. Despite the adoption of this conformation, there is no evidence for significant intramolecular C—H···π interactions. In terms of overall conformation, the structure of the title compound resembles that of the *n*-butyl (Qian *et al.*, 2006) and ethyl analogues (Nicolaï *et al.*, 2011). The crystal packing is stabilized by strong hydrogen bonds between the hydroxyl of the phenol group and the N-atom of the amine group (Fig. 2). Furthermore, molecules are connected into a three-dimensional array via N1—H1N···O3, N1—H2N···O3 and C2—H2···O1 intermolecular hydrogen-bonding interactions; see Table 1 for geometric parameters and symmetry operations.

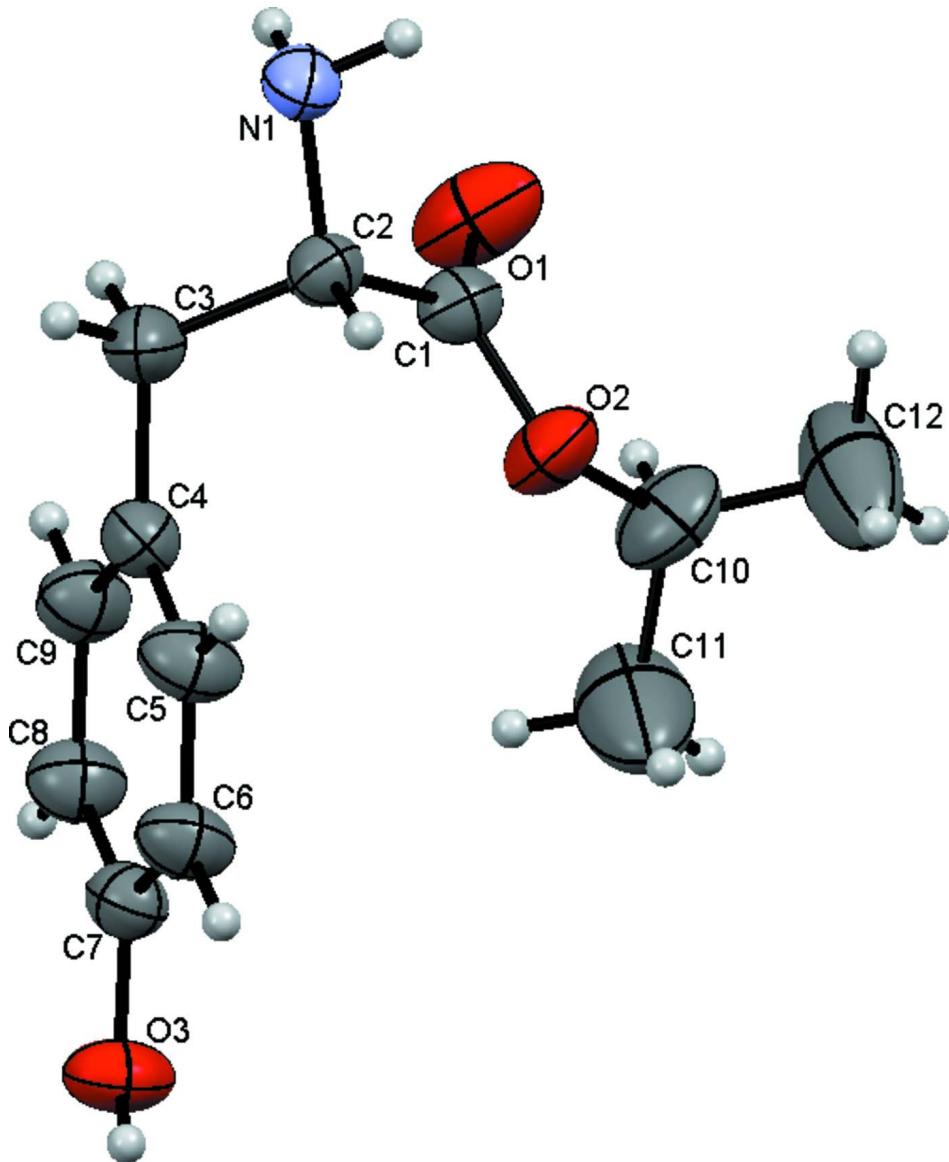

### S2. Experimental

Concentrated sulfuric acid (8 ml) was added to a suspension of *L*-tyrosine (10.00 g, 55.19 mmol) in isopropyl alcohol (40 ml). The mixture was heated at reflux and allowed to stir for 24 h. Then the reaction mixture was cooled to room temperature and placed into ice-cold water. The pH was brought to ~7 with concentrated ammonia, and isopropyl alcohol (40 ml) was added later to the reaction mixture. Precipitated ammonium sulfate was filtered off and washed with isopropyl alcohol (3×10 ml). The filtrate was concentrated under reduced pressure to a volume of 30 ml and single crystals were obtained by slow evaporation at room temperature. The title compound formed colorless prisms (5.50 g, 45%). m.p. 121–122 °C.

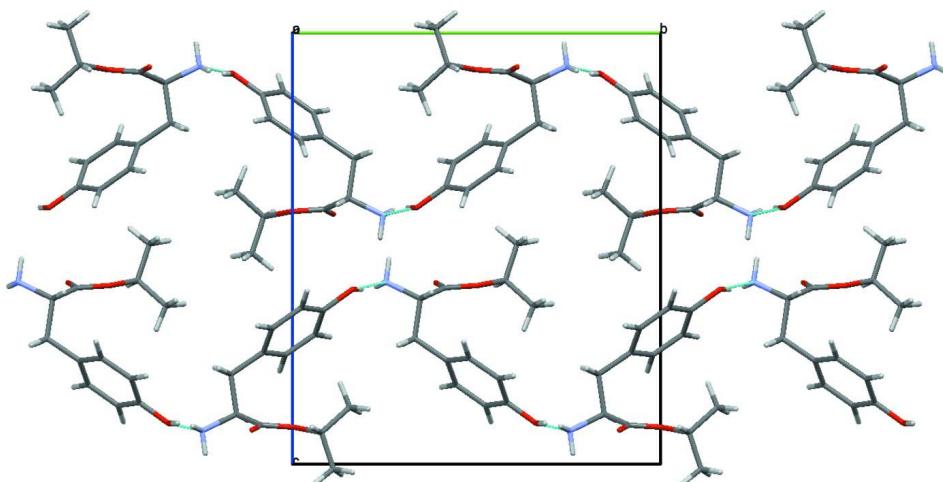

<sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>) δ 7.03 (d, *J* = 8.4 Hz, 2H), 6.69 (d, *J* = 8.4 Hz, 2H), 5.03 (hept, *J* = 6.3 Hz, 1H), 3.65 (dd, *J* = 7.7, 5.4 Hz, 1H), 3.01 (dd, *J* = 13.7, 5.3 Hz, 1H), 2.79 (dd, *J* = 13.8, 7.7 Hz, 1H), 1.25 (d, *J* = 6.2 Hz, 3H), 1.22 (d, *J* = 6.3 Hz, 3H). <sup>13</sup>C NMR (100 MHz, CD<sub>3</sub>OD) δ 21.9, 22.0, 41.1, 57.0, 69.7, 116.3, 128.9, 131.4, 157.4, 175.6. HRMS (ESI), *m/z* calcd for [C<sub>12</sub>H<sub>17</sub>NO<sub>3</sub>+H]<sup>+</sup> 224.1281; found: 224.1279 [M+H]<sup>+</sup>, 246.1094 [M+Na]<sup>+</sup>, 222.1088 [M—H]<sup>-</sup>.

**S3. Refinement**

The H atoms on N1 and O3 were located in a difference map and refined isotropically [refined distances: N—H = 0.88 (2) and 0.89 (3) Å, and O—H = 0.97 (4) Å]. All H atoms bound to C atoms were refined using a riding model, with C—H = 0.94–0.98 Å and  $U_{\text{iso}}(\text{H})$  = 1.2 or 1.5 times  $U_{\text{eq}}(\text{C})$ . In the absence of significant anomalous scattering effects, Friedel pairs have been merged in the final refinement.

**Figure 1**

Molecular structure of the title compound with displacement ellipsoids drawn at the 50% probability level. Hydrogen atoms are shown as spheres of arbitrary radius.

**Figure 2**

A view along the *a* axis of the crystal packing of the title compound. The O—H···N hydrogen bonds are shown as dashed cyan lines.

 $F_c^* = kFc[1 + 0.001xFc^2\lambda^3/\sin(2\theta)]^{-1/4}$   
Extinction coefficient: 0.059 (14)

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
