Received 19 November 2012; accepted 3 December 2012

Key indicators: single-crystal X-ray study; $T = 200$ K; mean $\sigma(\text{C-C}) = 0.005$ Å; R factor = 0.021; wR factor = 0.053; data-to-parameter ratio = 13.1.

In the structure of the title complex, $[\text{Cs}(\text{C}_6\text{H}_2\text{Cl}_3\text{N}_2\text{O}_2)\text{-(H}_2\text{O)}]_n$, the caesium salt of the commercial herbicide picloram, the Cs^+ cation lies on a crystallographic mirror plane, which also contains the coordinating water molecule and all non-H atoms of the 4-amino-3,5,6-trichloropicolinate anion except the carboxylate O-atom donors. The irregular CsCl_4O_5 coordination polyhedron comprises chlorine donors from the *ortho*-related ring substituents of the picloramate ligand in a bidentate chelate mode, with a third chlorine bridging [$\text{Cs}-\text{Cl}$ range 3.6052 (11)–3.7151 (11) Å] as well as a bidentate chelate carboxylate group giving sheets extending parallel to (010). A three-dimensional coordination polymer structure is generated through the carboxylate group, which also bridges the sheets down [010]. Within the structure, there are intra-unit water $\text{O}-\text{H}\cdots\text{O}_{\text{carboxylate}}$ and amine $\text{N}-\text{H}\cdots\text{N}_{\text{pyridine}}$ hydrogen-bonding interactions.

S1. Comment

4-Amino-3,5,6-trichloropyridine-2-carboxylic acid (picloram) is a commercial herbicide (Mullinson, 1985) introduced by Dow Chemicals as Tordon (O'Neil, 2001). Although it has potential as a metal chelating ligand similar to picolinic acid, there are only five metal complexes with picloramato ligands in the crystallographic literature. Examples include picloram as a bidentate chelate ligand [with Mn^{II} (Smith *et al.*, 1981*a*) and Cu^{II} (O'Reilly *et al.*, 1983)], while in the Mg complex (Smith *et al.*, 1981*b*), picloram acts as a counter-anion. A caesium complex derived from dipicolinic acid has also been reported (Santra *et al.*, 2011).

The reaction of picloram with caesium hydroxide in aqueous ethanol gave crystals of the title compound $[\text{Cs}(\text{C}_6\text{H}_2\text{Cl}_3\text{N}_2\text{O}_2)(\text{H}_2\text{O})]_n$ and the structure is reported herein. In this structure, the Cs⁺ cation lies on a crystallographic mirror plane which also contains the coordinating monodentate water molecule and all non-H atoms of the picloramate ligand except the carboxyl O-atom donors (Fig. 1). The irregular CsCl₄O₅ coordination sphere comprises chlorine donors from the *ortho*-related ring substituents (Cl5, Cl6) in a bidentate chelate mode [Cs—Cl, 3.6052 (11), 3.7151 (11) Å], with the third chlorine (Cl3) [Cs—Cl, 3.7127 (4) Å] bridging neighbouring Cs⁺ cations [Cs···Cs^x, Cs···Cs^{xi} = 4.9008 (3) Å] [for (x), -x + 1, y - 1/2, -z + 2; for (xi), -x + 1, y + 1/2, -z + 2], as well as a bidentate chelate and bridging carboxyl group. Although in most structures containing caesium and related ligands, the Cl atom is anionic rather than coordinating, an example of a coordinating carbon-bound Cl is known in which 1,2-dichloroethane acts as a bidentate chelate ligand (Levitskaia *et al.*, 2000). The Cs—Cl bond lengths in that structure are shorter than those in the title complex (3.46–3.56 Å).

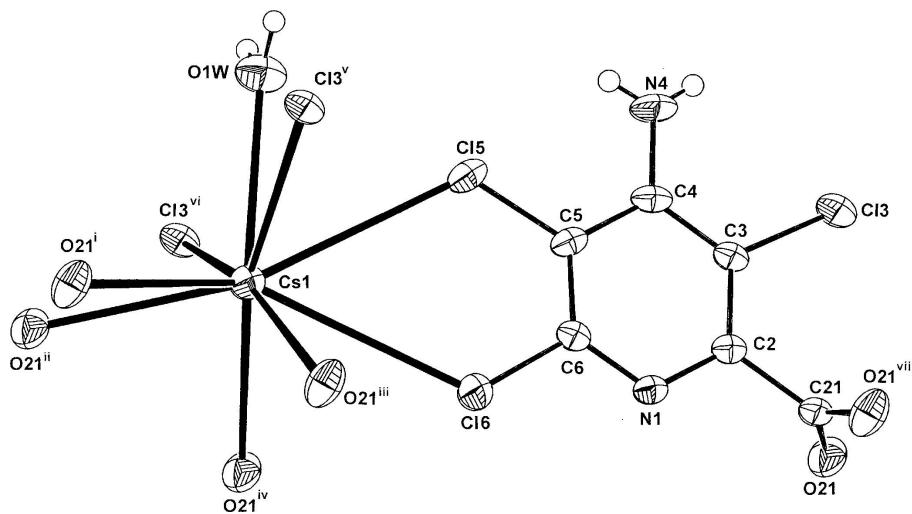

In the present complex, sheets are formed parallel to (010) (Fig. 2) and these are extended into a three-dimensional coordination polymer structure through the carboxyl group of the picloram ligand which bridges the sheets down [010] (Fig. 3). The amine group gives weak intramolecular N—H···Cl5 and ···Cl6 interactions and as well forms inter-complex N—H···N_{pyridine} hydrogen bonds which accompany water O—H···O_{carboxyl} hydrogen-bonding interactions in the structure (Table 2).

S2. Experimental

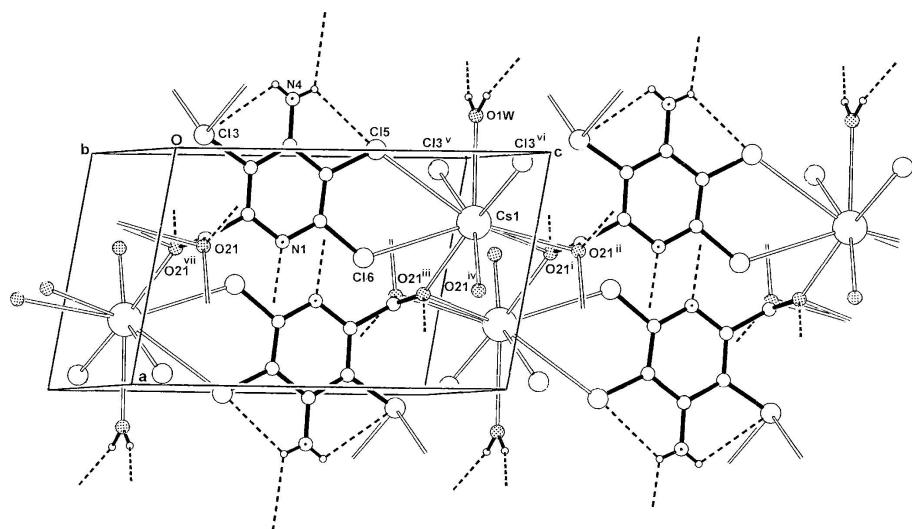

The title compound was synthesized by heating together under reflux for 10 minutes, 0.5 mmol of caesium hydroxide and 0.5 mmol of 4-amino-3,5,6-trichloropicolinic acid in 20 ml of 10% ethanol–water. Room temperature evaporation of the solution to incipient dryness gave colourless crystal plates of the title complex from which a specimen was cleaved for the X-ray analysis.

S3. Refinement

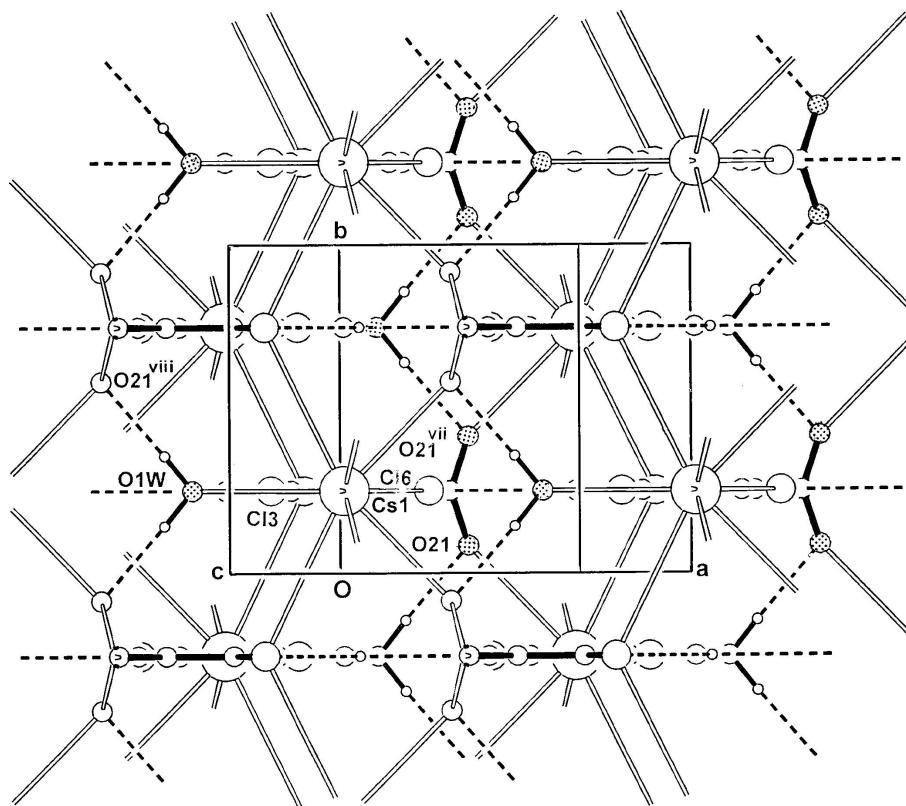

Hydrogen atoms of the coordinating water molecule and the amine group were located in a difference-Fourier synthesis but were allowed to ride in the refinement with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{N})$ or $1.5U_{\text{eq}}(\text{O})$.

**Figure 1**

The molecular configuration and atom-numbering scheme for the title compound, with non-H atoms drawn as 50% probability ellipsoids. For symmetry codes: see Table 1.

**Figure 2**

The sheet structure viewed perpendicular to the crystallographic mirror planes, with intermolecular hydrogen bonds and intramolecular N—H···Cl associations shown as dashed lines. For symmetry codes, see Fig. 1 and Table 1.

**Figure 3**

The packing in the unit cell viewed along the mirror planes showing inter-plane carboxyl bridges and hydrogen-bonding associations (Table 2) as dashed lines.

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
