> Key indicators: single-crystal X-ray study; $T=150 \mathrm{~K} ;$ mean $\sigma(\mathrm{C}-\mathrm{C})=0.003 \AA$; $R$ factor $=0.034 ; w R$ factor $=0.089 ;$ data-to-parameter ratio $=18.4$.

The molecule of the title compound, $\left[\mathrm{Ti}_{2}\left(\mathrm{CH}_{3}\right)_{2}\left(\mathrm{CH}_{3} \mathrm{O}\right)_{2^{-}}\right.$ $\left.\left(\mathrm{C}_{11} \mathrm{H}_{15} \mathrm{O}\right)_{4}\right]$ or $\left\{\left[\mathrm{Ti}(\mathrm{Me})\left(\mu-\mathrm{OCH}_{3}\right)\left(\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{CMe}_{3}-2-\mathrm{Me}-6\right)\right]_{2}\right\}$, has a centrosymmetric, dimeric structure with a distorted square pyramidal array about each titanium atom. The methoxide ligands form an asymmetric bridge between the two $\mathrm{Ti}^{\mathrm{IV}}$ atoms [ $\mathrm{Ti}-\mathrm{O}$ bond lengths of 1.9794 (12) and 2.0603 (12) A] with the two phenolato ligands occupying the remaining basal sites [ $\mathrm{Ti}-\mathrm{O} 1.8218$ (11) and 1.8135 (11) $\AA$ ]. The $\mathrm{Ti}-\mathrm{O}-\mathrm{C}$ phenolato bond angles are similar at 161.24 (10) and $160.66(11)^{\circ}$. The methyl ligand attached to the metal atom has a $\mathrm{Ti}-\mathrm{C}$ bond length of 2.0878 (17) $\AA$.

## S1. Comment

Titanium complexes containing phenolato ligands (OAr) or alkoxo ligands (OR) as well as an alkyl ligand have been described (Janas et al. 2005; Janas et al. 2004; Zhang 2007a,b; Kobylka et al. 2007) but complexes containing both oxygen ligand sets and an alkyl ligand are not known. The chemistry of phenolato and alkylato complexes has been known for many years (Bradley et al. 1978) and in particular alkoxy bridged bis-phenolato dititanium complexes have been prepared (Ejfler et al. 2004). Several examples of X-ray crystal structures for titanium complexes containing terminal and bridging phenolato ligands have been reported (Gowda et al. 2009; Nielson et al. 2006; Svetich \& Voge, 1972). During attempts to form bis-dimethyl bis-phenolato complexes of titanium for testing as olefin oligomerization and polymerization catalysts, in one case we reacted $\left[\mathrm{TiCl}_{2}\left(\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{CMe}_{3}-2-\mathrm{Me}-6\right)_{2}\right]$ (Nielson et al. 2005; Santora et al. 1999) with two equivalents of methylmagnesium iodide and recrystallized the resulting product from petroleum spirit at low temperatures for a period of several months. A nice crystalline red coloured product was formed which was expected to be the bis-dimethyl complex $\left[\mathrm{Ti}(\mathrm{Me})_{2}\left(\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{CMe}_{3}-2-\mathrm{Me}-6\right)_{2}\right]$. However the X-ray crystal structural analysis showed it was the dimeric methoxy bridged complex $\left[\left\{\mathrm{Ti}(\mathrm{Me})(\mu-\mathrm{OMe})\left(\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{CMe}_{3}-2-\mathrm{Me}-6\right)_{2}\right\}_{2}\right]$ (1). Alkyl complexes of transition metal complexes are usually air sensitive and it was expected that the methoxo ligand had resulted from moist air entering the crystallization flask adventiciously and either water or oxygen inserting into a $\mathrm{Ti}-\mathrm{CH}_{3}$ bond. A reaction where oxygen inserts into a $\mathrm{Ti}-\mathrm{CH}_{3}$ bond has been reported (Zhang et al., 2007a).
The structure of (1) is centrosymmetric and consists of an asymmetric, methoxy bridged dimer in which each Ti centre has two terminal phenolato ligands and a methyl ligand attached (Fig. 1). Each titanium atom has a distorted square pyramidal geometry in which the base of the square pyramid is made up by the oxygen atoms of the two cis-related terminal phenolato ligands and the oxygen atoms of the methoxy bridging system. A similar distorted square pyramidal structure is found in $\left[\{(\mathrm{tbop}) \mathrm{Ti}(\mathrm{Me})\}_{2}(\mu-\mathrm{OMe})_{2}\right]$ (tbop $=2,2$-thiobis $\{4-(1,1,3,3-$ tetramethylbutyl)phenol $\}$ (Janas et al. 2005). The distortion in (1) is such that the $O$ atom of one phenolato ligand and the trans-related oxygen of the methoxy bridge has a nearly linear disposition with the $\mathrm{O}(1)-\mathrm{Ti}-\mathrm{O} 3^{\mathrm{i}}$ bond angle at $162.64(5)^{\circ}$. The other phenolato ligand oxygen and its trans-related methoxy ligand oxygen form a much more bent system where the $\mathrm{O}(2)-\mathrm{Ti}-\mathrm{O}(3)$ bond angle is $138.00(5)^{\circ}$.

The two Ti atoms and the methoxide ligand oxygen atoms of the oxygen bridges $\left(\mathrm{O} 3, \mathrm{O}^{i}\right)$ are coplanar with O 1 and $\mathrm{Ol}^{1}$ lying on either side of the plane with displacements of 0.0234 (2) $\AA$. The remaining oxygen of the square pyramidal base is displaced by -1.134 (2) $\AA$.
The methyl group (C24) of the complex occupies the apical site of the square plane as similarly found in $\left[\left\{(\mathrm{tbop}) \mathrm{Ti}(\mathrm{Me}\}_{2}(\mu-\mathrm{OMe})_{2}\right]\right.$ (Janas et al. 2005). The distortion away from the square plane is also shown by the various $\mathrm{C} 24-\mathrm{Ti}-$ bond angles. The $\mathrm{C} 24-\mathrm{Ti}-\mathrm{O}\left(3^{\mathrm{i}}\right)$ bond angle which involves the oxygen of the methoxy bridge is $90.33(6)^{\circ}$ whereas for the trans-related oxygen, $\mathrm{O}(1)$, which involves the phenolato ligand, the angle is $97.38(7)^{\circ}$ indicating that this oxygen pushes slightly closer to the methyl group than does the bridging oxygen. For the other bridging methoxy
ligand the $\mathrm{C}(24)-\mathrm{Ti}-\mathrm{O}(3)$ bond angle is $112.91(6)^{\circ}$ and the $\mathrm{C}(24)-\mathrm{Ti}-\mathrm{O}(2)$ bond angle involving the phenolato ligand oxygen is $104.51(7)^{\circ}$ indicating that this oxygen pushes slightly closer to the methyl group than the bridging oxygen. The angles associated with the $\mathrm{C}(24)-\mathrm{Ti}-\mathrm{O}$ system thus show that for the methoxy bridge the $\mathrm{C}(24)-\mathrm{Ti}-\mathrm{O}(3)$ bond angle [112.91 (6) ${ }^{\circ}$ ] opens out considerably more than does the $\mathrm{C}(24)-\mathrm{Ti}-\mathrm{O}\left(3^{\mathrm{i}}\right)$ bond angle $\left[90.33(6)^{\circ}\right]$. The $\mathrm{C}(24)-\mathrm{Ti}-\mathrm{O}$ angles associated with the phenolato ligand are also very different with the $\mathrm{C}(24)-\mathrm{Ti}-\mathrm{O}(2)$ bond angle [104.51 (7) ${ }^{\circ}$ ] opened out more than the $\mathrm{C}(24)-\mathrm{Ti}-\mathrm{O}(1)$ bond angle [97.38 (7) ${ }^{\circ}$ ].
The methoxy bridging system has a $\mathrm{Ti}-\mathrm{O}-\mathrm{Ti}^{\mathrm{i}}$ bond angle of $109.03(5)^{\circ}$, an $\mathrm{O}(3)-\mathrm{Ti}-\mathrm{O}\left(3^{\mathrm{i}}\right)$ bond angle of 70.97 (5) ${ }^{\circ}$ with $\mathrm{Ti}-\mathrm{O}(3)-\mathrm{C}(23)$ and $\mathrm{Ti}-\mathrm{O}(3)-\mathrm{C}\left(23^{\mathrm{i}}\right)$ bond angles of $129.10(10)$ and $121.77(10)^{\circ}$ respectively which are similar to those found in other alkoxy bridged titanium dimers (Janas et al. 2005, 2004) The separation between the phenolato ligands is shown by the $\mathrm{O}(1)-\mathrm{Ti}-\mathrm{O}(2)$ angle of $102.02(5)^{\circ}$ which is much wider than the $\mathrm{O}(3)-\mathrm{Ti}-\mathrm{O}\left(3^{\mathrm{i}}\right)$ angle associated with the methoxy bridge $\left[70.97(5)^{\circ}\right]$ which means that the bridging system is compressed in comparison to the terminal phenolato ligands. This no doubt occurs since there is significant repulsion between the aromatic rings. However the two terminal phenolato ligand O atoms push away from the cis-related methoxo bridge O atoms to nearly equal extents $\left[\mathrm{O}(1)-\mathrm{Ti}-\mathrm{O}(3)\right.$ and $\mathrm{O}(2)-\mathrm{Ti}^{i}-\mathrm{O}\left(3^{i}\right)$ bond angles 91.68 (5) and 90.97 (5) ${ }^{\circ}$ respectively].
The aromatic rings of the cis-related phenolato ligands are rotated away from each other with the $\mathrm{Ti}-\mathrm{O}(1)-\mathrm{C}(1)$ and $\mathrm{Ti}-$ $\mathrm{O}(2)-\mathrm{C}(12)$ bond angles being nearly equal $\left[161.24(10)\right.$ and $\left.160.66(11)^{\circ}\right]$. In comparison, the related bridging trisphenolato complex $\left[\left\{\mathrm{TiCl}\left(\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{Me}_{2}-2,4\right)_{2}\left(\mu-\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{Me}_{2}-2,4\right)\right\}_{2}\right]$ has one terminal phenolato ligand $\mathrm{Ti}-\mathrm{O}-\mathrm{C}$ bond angle nearly linear [171.4 (1) ${ }^{\circ}$ ] and the other much more bent [ $\mathrm{Ti}-\mathrm{O}-\mathrm{C}$ bond angle 138.8 (1) ${ }^{\circ}$ ] (Nielson et al. 2006). Although these angles are essentially the same in (1), one phenyl ring is rotated so that its face points inwards towards the other but slightly down and the other ring is rotated so that it points away from and slightly down from the former. The rotation is such that the tert-butyl substituents in the 2-position of the phenyl ring lie adjacent to each other, as do the two methyl substituents on the phenyl ring 6-position. For the two adjacent tert-butyl substituents the methyl carbons are related by a geared disposition which apparently allows a further gearing across the two substituents of the attached hydrogen atoms. Two methyl groups of both tert-butyl substituents also have a geared disposition with the adjacent carbon atom [C(24)] of the Ti methyl group.
The methoxy bridging system is asymmetric with the Ti-O(3) bond length [1.9794 (12) $\AA$ ] significantly shorter than the $\mathrm{Ti}-\mathrm{O}\left(3^{\mathrm{i}}\right)$ bond length $[2.0603(12) \AA$ ]. For the $\mathrm{Ti}-\mathrm{O}$ bond lengths associated with the phenolato ligands the $\mathrm{Ti}-\mathrm{O} 1$ and $\mathrm{Ti}-$ O2 bond lengths [1.8218 (11) and 1.8135 (11) Å respectively] differ only slightly from one another but are significantly shorter than the methoxy bridge system $\mathrm{Ti}-\mathrm{O}$ bond lengths. These shorter bond lengths indicate that the phenolato ligands are the better $\pi$-donors to the metal and this is supported by the nearly linear $\mathrm{Ti}-\mathrm{O}-\mathrm{C}$ bond angles associated with them. In comparison the related bridging tris-phenolato complex [ $\left.\left\{\mathrm{TiCl}\left(\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{Me}_{2}-2,4\right)_{2}\left(\mu-\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{Me}_{2}-2,4\right)\right\}_{2}\right]$ has one short $\mathrm{Ti}-\mathrm{O}$ phenolato ligand bond length $\left[1.757\right.$ (1) $\AA$ ] which is related to the near linear $\mathrm{Ti}-\mathrm{O}-\mathrm{C}$ bond angle $\left[171.4(1)^{\circ}\right]$ and thus is the stronger $\pi$-donor and one longer Ti-O phenolato ligand bond length [1.794 (2) $\AA$ ] related to the more bent Ti -$\mathrm{O}-\mathrm{C}$ bond angle $\left[138.8(1)^{\circ}\right]$ and the poorer $\pi$-donor (Nielson et al.. 2006). The $\mathrm{Ti}-\mathrm{O}-\mathrm{C}$ bond angles associated with the asymmetric methoxy bridging system are much reduced in comparison [129.10(10) and $\left.121.77(10)^{\circ}\right]$ indicating the reduced $\pi$-donor ability in this coordination mode. Terminal alkoxo ligands have much shorter bond lengths and larger $\mathrm{Ti}-\mathrm{O}-\mathrm{C}$ bond angles and are usually stronger $\pi$-donor ligands than phenolato ligands which have the ability for competitive $\pi$-back-donation to the aromatic ring. However in all cases involving phenolato and alkoxo ligands there is a subtle interplay of the $\pi$-donor properties depending on coordination mode and geometry. $\mathrm{The} \mathrm{Ti}-\mathrm{C}$ bond length for the Ti $-\mathrm{CH}_{3}$ ligand $\left[2.0878(17) \AA\right.$ ] is similar to the $\mathrm{Ti}-\mathrm{C}$ bond length $\left[2.078(4) \AA\right.$ ] found in [ $\left.\{(\operatorname{tbop}) \mathrm{Ti}(\mathrm{Me})\}_{2}(\mu-\mathrm{OMe})_{2}\right]$ (Janas et al. 2005).

## S2. Experimental

Methyl magnesium iodide ( 11.8 ml of a $1.076 \mathrm{~mol} / 1$ solution, 12.7 mmole ) in diethyl ether was added dropwise to a stirred suspension of $\left[\mathrm{TiCl}_{2}\left(\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{CMe}_{3}-2-\mathrm{Me}-6\right)_{2}\right](2.41 \mathrm{~g}, 5.79 \mathrm{mmole})$ in petroleum spirit (boiling point 40-60 $)$ cooled in a dry-ice bath. The dry-ice bath was removed and the mixture stirred overnight. The solution was filtered, solvent removed and the residue extracted with hot petroleum spirit to give an orange-red solution. Reduction of the solvent volume and standing at $-20^{\circ} \mathrm{C}$ gave a small quantity of the product as orange-red crystals. Found: C, $68.24 ; \mathrm{H}$, 9.10. $\mathrm{C}_{48} \mathrm{H}_{72} \mathrm{O}_{6} \mathrm{Ti}_{2}$ requires $\mathrm{C}, 68.56 ; \mathrm{H}, 8.63$. A crystal was chosen and the X -ray single crystal structure obtained.

## S3. Refinement

All H atoms were included in calculated positions and refined using a riding model $\left[U(\mathrm{H})_{\text {eq }}=1.2 U \mathrm{C}_{\text {eq }}\right.$ for aromatic CH and $U(\mathrm{H})=1.5 U(\mathrm{C})$ for methyl H atoms]. C -H distances of $0.96 \AA$ and $0.93 \AA$ were assumed for aromatic and methyl groups respectively.

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving 1.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors(gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$-factors based on ALL data will be even larger.
