Received 5 February 2014; accepted 10 February 2014

Key indicators: single-crystal X-ray study;  $T = 200\text{ K}$ ; mean  $\sigma(\text{C}-\text{C}) = 0.003\text{ \AA}$ ; disorder in main residue;  $R$  factor = 0.041;  $wR$  factor = 0.114; data-to-parameter ratio = 15.3.

There are two independent molecules in the asymmetric unit of the title compound,  $\text{C}_{12}\text{H}_{15}\text{N}_3\text{S}$ , both of which display disorder of several C atoms in the N-bound ring (occupancy ratios of 0.75:0.25 in the first independent molecule and 0.50:0.50 in the second) with the methyl H atoms also being disordered in the first molecule (occupancy ratio of 0.70:0.30). The planes of the benzene ring and the N–N–C–N fragment make dihedral angles of  $12.92(14)^\circ$  in the first independent molecule and  $7.60(13)^\circ$  in the second. In the crystal, molecules are linked by weak N–H···S hydrogen bonds into chains along the  $a$ -axis direction. The crystal packing resembles a herringbone arrangement.

## N-Methyl-2-(1,2,3,4-tetrahydronaphthalen-1-ylidene)hydrazinecarbothioamide

Adriano Bof de Oliveira, Bárbara Regina Santos Feitosa, Christian Näther and Inke Jess

### S1. Comment

Thiosemicarbazone derivatives have been used as ligands in coordination chemistry as well as for applications in biological systems, because some of them shows antifungal, antibacterial and anticancer properties (Lobana *et al.*, 2009). As part of our study on thiosemicarbazone compounds, we report herein the crystal structure of a tetralone thiosemicarbazone derivative.

In the crystal structure of the title compound, there are two crystallographically independent molecules on the asymmetric unit in general positions, in which some of the C, and H atoms are disordered (Fig. 1). For one crystallographic independent molecule, the dihedral angle between the benzene ring (C5—C10) and the N1—N2—C11—N3 fragment amounts to 12.92 (14)° and for the second crystallographically independent molecule the dihedral angle between the benzene ring (C25—C30) and the N21—N22—C31—N23 fragment amounts to 7.60 (13)°. So, the molecules do not only show a different kind of disorder, but differ also in the molecular geometry.

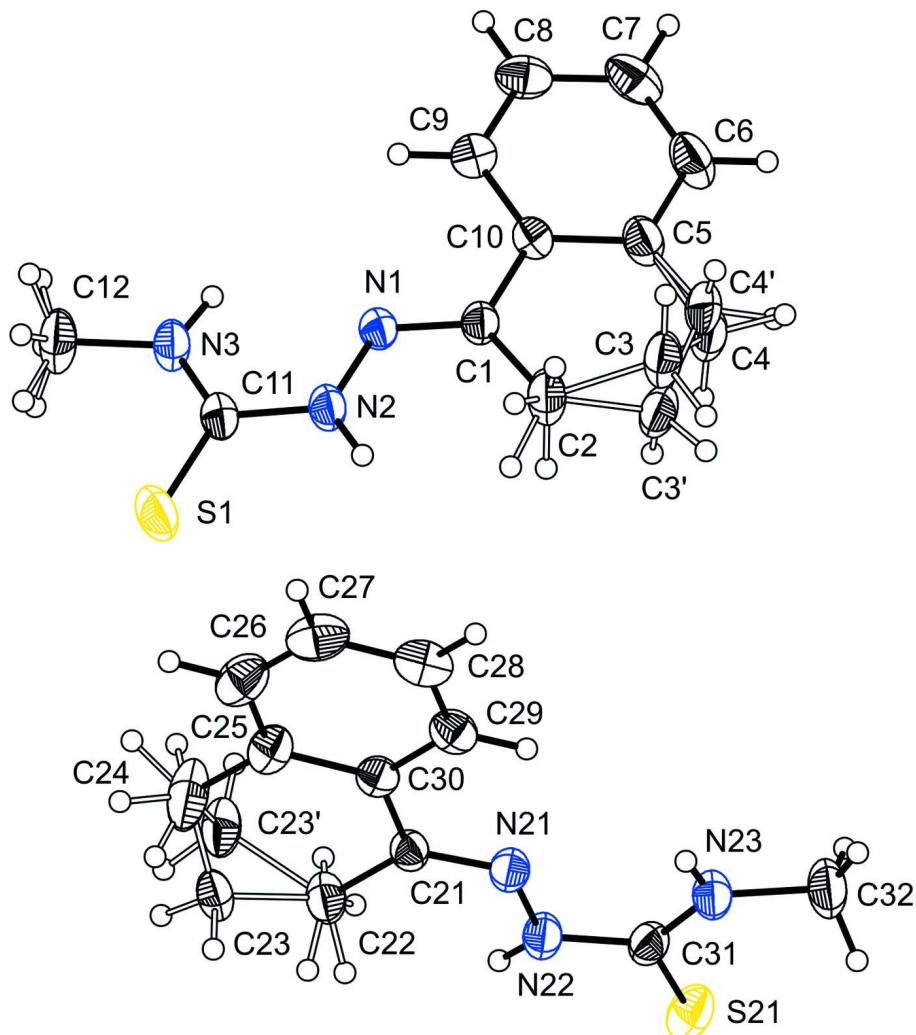

In the crystal, the molecules are linked by long weak N—H···S hydrogen bonding into chains that run along the *a*-axis. The S···H distances amount to 3.02 (2) Å for the S1 and 3.291 (22) Å for the S21 atoms (Table 1). When viewed along the *c*-axis (Fig. 2), the molecules show a herringbone motif.

### S2. Experimental

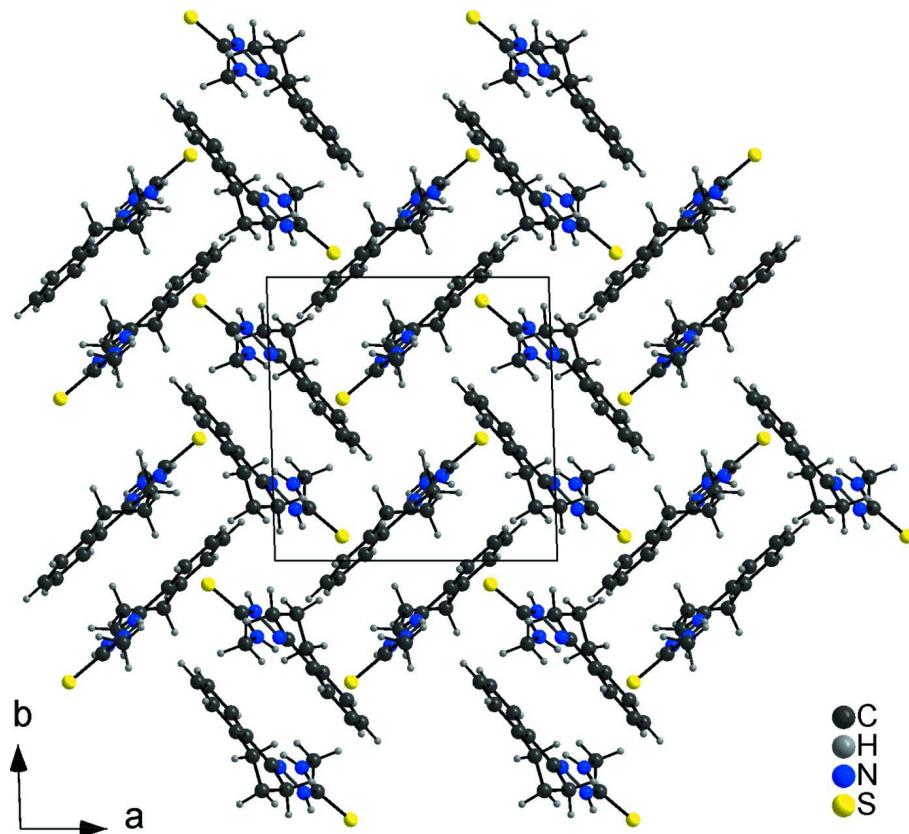

Starting materials were commercially available and were used without further purification. The tetralone-thiosemicarbazone derivative synthesis was adapted from a procedure reported previously (Freund & Schander, 1902). The hydrochloric acid catalyzed reaction of tetralone (8,83 mmol) and 4-methylthiosemicarbazine (8,83 mmol) in ethanol (50 ml) was refluxed for 6 h. After cooling and filtering, the title compound was obtained as a solid. Crystals suitable for X-ray diffraction of the title compound were obtained in tetrahydrofuran by the slow evaporation of solvent.

### S3. Refinement

All non-hydrogen atoms were refined anisotropic. All H atoms were located in difference map but were positioned with idealized geometry (methyl H atoms allowed to rotate but no to tip) and were refined isotropic with  $U_{\text{iso}}(\text{H}) = 1,2 U_{\text{eq}}(\text{C})$  (1,5 for methyl H atoms) using a riding model with C—H = 0,95 Å for aromatic and C—H = 0,99 Å for methylene. The N—H H atoms were located in difference map and refined with varying coordinates and varying isotropic displacement parameters. There are two crystallographically independent molecules in the asymmetric unit. In both of them several C atoms disordered (C3, C4 and C23) and were refined using a split model. The methyl C12 H atoms are disordered and were refined in two orientations.

**Figure 1**

The molecular structure of the title compound with labeling and displacement ellipsoids drawn at the 40% probability level. Disorder is shown with full and open bonds.

**Figure 2**

Crystal structure of the title compound viewed along the *c*-axis. The disorder is not shown for clarity.

$$\Delta\rho_{\min} = -0.42 \text{ e } \text{\AA}^{-3}$$

*Special details*

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) etc. and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
