Key indicators: single-crystal X-ray study; $T = 293\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.005\text{ \AA}$;
 R factor = 0.031; wR factor = 0.084; data-to-parameter ratio = 17.1.

The structure of the title compound, $(\text{C}_7\text{H}_{10}\text{N})_4[\text{H}_2\text{V}_{10}\text{O}_{28}] \cdot 2\text{H}_2\text{O}$, was solved from a non-merohedrally twinned crystal (ratio of twin components $\sim 0.6:0.4$). The asymmetric unit consists of one-half decavanadate anion (the other half completed by inversion symmetry), two 2,6-dimethylpyridinium cations and one water molecule of crystallization. In the crystal, the components are connected by strong $\text{N}-\text{H} \cdots \text{O}$ and $\text{O}-\text{H} \cdots \text{O}$ hydrogen bonds, forming a supramolecular chain along the b -axis direction. There are weak $\text{C}-\text{H} \cdots \text{O}$ interactions between the chains.

Tetrakis(2,6-dimethylpyridinium) dihydrogen decavanadate dihydrate

Erik Rakovský and Lukáš Krivosudský

S1. Comment

The reaction system V_2O_5 – 2,6-dimethylpyridine – H_2O – $HClO_4$ was studied as a part of our study of the formation of transition metal complexes with substituted pyridinium ligands in the presence of polyoxovanadate anions. We wish to obtain a better understanding of the role of the counter-ion in the formation of $H_nV_{10}O_{28}^{(6-n)-}$ species and the influence of the cation and the decavanadate anion protonation mode on the IR spectra and information about possible side products of the syntheses. This article is a continuation of our previous work on salts of polyoxovanadates with organic cations (Rakovský & Gyepes, 2006; Pacigová *et al.*, 2007). The oxovanadates(V) and peroxovanadium compounds are also of great interest in biochemistry and medicine because of their diverse biological activities (Crans, 1998). Heterobimetallic compounds containing, beside polyoxovanadate core, entities composed of other transition metals bound to organic ligands have been extensively studied due to their potential applications in the field of catalysis and material science (Hagman *et al.*, 2001; Klišincová *et al.*, 2008; Klišincová *et al.*, 2010; Bartošová *et al.*, 2012). Several decavanadates with pyridine and its derivatives are already known. Asgedom *et al.* (1996) reported the structure of $(C_5H_6N)_6V_{10}O_{28} \cdot 2H_2O$. Pyridinium cations are bonded directly to the decavanadate anions *via* hydrogen bonds as it is in $(C_7H_{10}N)_3H_3V_{10}O_{28} \cdot H_2O$ (Arrieta *et al.*, 1988) and $(C_6H_8N)_3H_3V_{10}O_{28} \cdot H_2O$ (Santiago *et al.*, 1988).

The system mentioned above was studied in the pH range 2.5–7 and the crystalline product was only obtained at pH 2.5, which is typical pH value for the dihydrogendifcavanadate formation. The asymmetric unit of the title compound, (I), consists of one-half decavanadate anion of C_i symmetry, lying on a special position on the centre of symmetry, which is protonated on the μ -OV₃ bridging atom O13, two 2,6-dimethylpyridinium cations and one water molecule of crystallization (Fig. 1). The terminal vanadium-oxygen bond lengths are in the range 1.5916 (17)–1.6153 (16) Å, with an average value of 1.601 (10) Å. The bond lengths of the bridging O atoms with coordination numbers two are in the range 1.6768 (14)–2.0752 (15) Å with the mean value of 1.84 (12) Å. There are 2 types of μ -OV₃ bridging oxygen groups present: unprotonated (O12) with bond lengths in the range 1.8757 (15)–1.9931 (14) Å with the mean value of 1.95 (6) Å, and protonated (O13) with bond lengths in the range 2.0678 (15)–2.1170 (14) Å with the mean value of 2.10 (3) Å. Bond lengths of the six-coordinated μ -OV₆ oxygen atom (O14) are in the range 2.0592 (13)–2.3588 (14) Å with an average value of 2.24 (13) Å.

The supramolecular structure is formed by $D-H\cdots O$ hydrogen bonds [$D = N, O$ or C , with $H\cdots O \leq 2.72$ Å and $D-H\cdots O > 120^\circ$ (Jeffrey, 1997)] between cations and anions, cations and water molecules, between two anions and between water molecules and anions (Table 1). Adjacent $[H_2V_{10}O_{28}]^4-$ anions are mutually linked together by the system of strong hydrogen bonds: directly by two anion-anion hydrogen bonds O13–H1V…O1 and *via* two bridging water molecules, where water acts as a H-bond donor for both anions, forming O1W–H1W…O11 and O1W–H2W…O8 hydrogen bonds. N–H group of the first cation is donating H-bond to the anion, thus forming N1–H10…O9 hydrogen bond, N–H group of the second cation acts as a H-bond donor for the water molecule, forming N2–H20…O1W hydrogen bond. This system of hydrogen bonds is forming supramolecular chain running in the *b* axis direction (Fig. 2).

The C–H···O weak hydrogen bonds present in the structure are involved in the interaction between neighbouring supramolecular chains, with exception of C21–H21B···O5 and C27–H27B···O1 bonds, which are reinforcing mutual bonding between one of the anions, cation and the water molecule hydrogen-bonded to the cation.

S2. Experimental

All reactants with the exception of purified vanadium pentoxide were obtained commercially and used without further purification.

Purified vanadium pentoxide was prepared as follows: to 1.5 l of water, NH_4VO_3 (50 g) and NH_3 (60 ml, $w = 25\%$) were added. The mixture was stirred and heated in a water bath until the temperature reached 343 K and left cool down for about 1 h. After cooling the mixture was filtered. White NH_4VO_3 was precipitated by adding of crystalline NH_4NO_3 (70 g) to the filtrate, filtered out and washed with distilled water (20 ml) and ethanol (20 ml). The product was dried on air.

Purified NH_4VO_3 was heated in a porcelain dish at 773 K for at least 2 h.

Test for purity of prepared V_2O_5 : small amount of the product added to cold 1 M solution of KOH in a test tube completely dissolves.

Synthesis of the $(\text{C}_7\text{H}_{10}\text{N})_4\text{H}_2\text{V}_{10}\text{O}_{28} \cdot 2\text{H}_2\text{O}$ (I): V_2O_5 (0.9 g, 0.005 mol) was dissolved after stirring overnight in 100 ml of 0.1 M solution of 2,6-dimethylpyridine. Yellow solution obtained was filtered and adjusted to pH 2.5 with 4 M HClO_4 . Orange plate crystals were isolated after standing 5 days at 277 K.

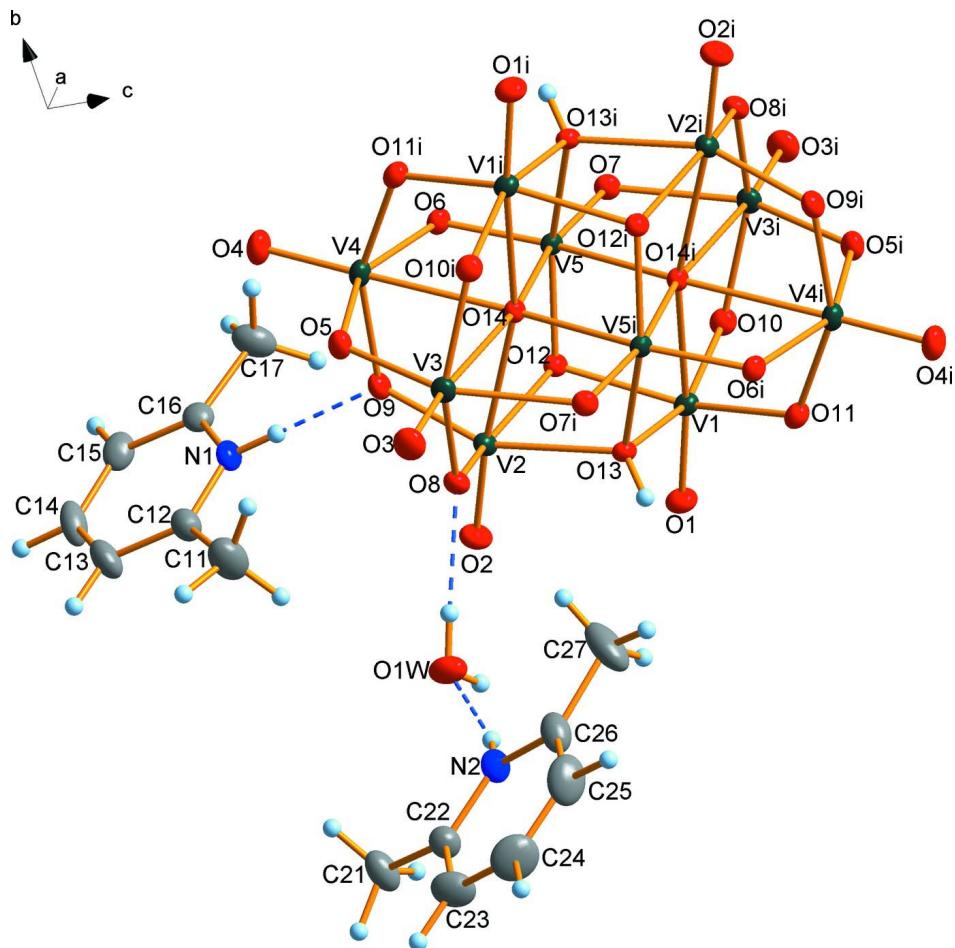

Vanadium was determined gravimetrically as V_2O_5 . C, H and N were estimated on a CHN analyser (Carlo Erba). Analysis calculated for $\text{C}_{28}\text{H}_{46}\text{N}_4\text{O}_{30}\text{V}_{10}$ (found): C 23.55 (23.59), H 3.25 (3.21), N 3.92 (3.89), V 35.67 (35.58).

The FT—IR spectra were performed with a Nonius 6700 FTIR spectrophotometer in nujol mulls. The IR spectrum of prepared compound exhibits characteristic bands of the decavanadate anion [965 (*s*), 944 (*s*), 926 (*m*), 829 (*s*) and 589 (*m*) cm^{-1}] (Klištincová *et al.*, 2010) as well as characteristic bands for protonated 2,6-dimethylpyridine (2534 (*sh*) – $\nu(\text{NH}^+)$; 1629 (*s*), 1641 (*s*) – $\delta(\text{NH}^+)$) and other bands for the base (716 (*s*), 794 (*s*) – $\delta(\text{CH})$; 971 (*s*) – $\nu(\text{C}-\text{CH}_3)$; 1175 (*m*), 1280 (*m*) – $\delta(\text{CH comb.})$, 1415 (*m*) – $\nu(\text{C}-\text{C})$ or $\nu(\text{C}-\text{N})$) (Ban-Oganowska *et al.*, 2002; Elassal *et al.*, 2011; Medhi *et al.*, 1965).

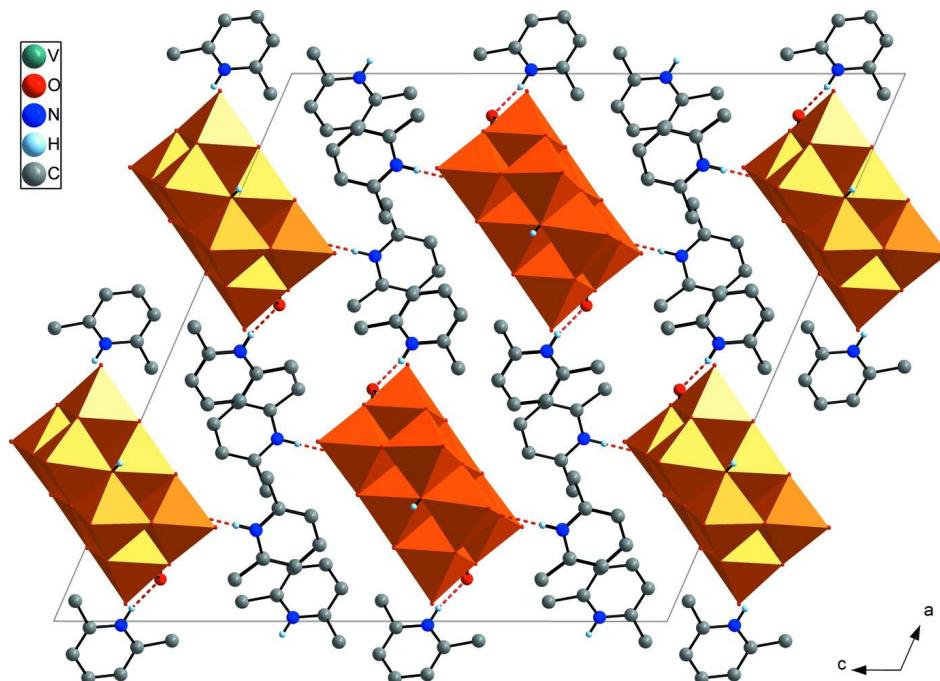

S3. Refinement

The selected crystal was a non-merohedral twin with the twin law: -1 0 0; 0 -1 0; 1 0 1 (given by rows) and the domain volume ratio approx. 0.6:0.4. The structure was solved and refined from detwinned HKLF 4 data, however, due to approximately equal domain volume ratio, some reflections were strongly affected (typically $F_o >> F_c$) by twinning; these reflections were omitted in the final stages of the refinement.

The H atoms bound to the C atoms of the cations were placed in geometrically idealized positions ($\text{C}-\text{H} = 0.93 \text{ \AA}$) and constrained to ride on their parent atoms [$U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$] with the exception of the methyl groups, which were treated as rigid rotors [$\text{C}-\text{H} = 0.96 \text{ \AA}$, $U_{\text{iso}}(\text{H}) = 1.5 U_{\text{eq}}(\text{C})$]. The H atoms bound to N atoms were refined semi-freely using distance restraint ($\text{N}-\text{H} = 0.86$ (2) \AA) and with $U_{\text{iso}}(\text{H}) = 1.5 U_{\text{eq}}(\text{N})$. The H atoms of the anion and water molecule were located in a difference map and refined with $d(\text{O}-\text{H}) = 0.82$ (2) \AA and $d(\text{H}\cdots\text{H}) = 1.36$ (2) \AA for water molecule.

**Figure 1**

The structure of the title compound, showing the atom labelling scheme and hydrogen bonding interactions (dashed lines). Displacement ellipsoids are drawn at the 30% probability level. The symmetry operation: (i) $3/2 - x, 3/2 - y, 1 - z$.

**Figure 2**

A view of the cell packing of (I) along the b axis. Supramolecular chains are running in the b axis direction, $\text{N}-\text{H}\cdots\text{O}$ and $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonds are drawn as red dashed lines. Carbon-bound hydrogen atoms are omitted for clarity.

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
