Received 16 May 2014; accepted 11 June 2014

Key indicators: single-crystal X-ray study; $T=293 \mathrm{~K}$; mean $\sigma(\mathrm{P}-\mathrm{O})=0.003 \AA$; disorder in main residue; $R$ factor $=0.040 ; w R$ factor $=0.095$; data-to-parameter ratio $=23.6$.

The title compound, tetrapotassium tetra[nickel(II)/iron(III)] pentakis(orthophosphate), $\mathrm{K}_{3.84} \mathrm{Ni}_{0.78} \mathrm{Fe}_{3.19}\left(\mathrm{PO}_{4}\right)_{5}$, has been obtained from a flux. The structure is isotypic with that of $\mathrm{K}_{4} \mathrm{MgFe}_{3}\left(\mathrm{PO}_{4}\right)_{5}$. The three-dimensional framework is built up from $(\mathrm{Ni} / \mathrm{Fe}) \mathrm{O}_{5}$ trigonal bipyramids with a mixed $\mathrm{Fe}: \mathrm{Ni}$ occupancy of 0.799 (8):0.196 (10) and isolated $\mathrm{PO}_{4}$ tetrahedra, one of which is on a general position and one of which has $\overline{4}$. . site symmetry. Two $\mathrm{K}^{+}$cations are statistically occupied and are distributed over two positions in hexagonally shaped channels that run parallel to [001]. One $\mathrm{K}^{+}$cation [occupancy 0.73 (3)] is surrounded by nine O atoms, while the other $\mathrm{K}^{+}$ cation [occupancy 0.23 (3)] is surrounded by eight O atoms.

## Related literature

## S1. Comment

Complex iron-containing phosphates have different applications, for example as ionic conductors (Fisher et al., 2008), cathode materials (Barpanda et al., 2012; Trad et al., 2010) and matrices for storage of nuclear waste (Huang et al., 2005; Shih, 2003). In the crystal structures of these compounds the iron cations can adopt different coordination numbers and hence different oxygen polyhedra: $\mathrm{FeO}_{4}$ (Hidouri et al., 2002), $\mathrm{FeO}_{5}$ (Hidouri et al., 2003) or $\mathrm{FeO}_{6}$ (Lajmi et al., 2002). Herein, the structure of the solid solution $\mathrm{K}_{3.84} \mathrm{Ni}_{0.78} \mathrm{Fe}_{3.19}\left(\mathrm{PO}_{4}\right)_{5}$, tetrapotassium tetra(nickel(II)/iron(III)) pentakis(orthophosphate), (I), is reported. The crystal structure of (I) is isotypic with $\mathrm{K}_{4} \mathrm{MgFe}_{3}\left(\mathrm{PO}_{4}\right)_{5}$ (Hidouri et al., 2008).
The asymmetric unit of (I) consists of one mixed-occupied ( $\mathrm{Ni}^{\mathrm{II}} / \mathrm{Fe}^{\mathrm{II}}$ ) site, two P sites (one of which is located on a fourfold rotoinversion axis), five oxygen sites and two $\mathrm{K}^{+}$sites which are partly occupied and distributed over two positions (K1A and K1B) (Fig. 1). The main building blocks are one $\left[\left(\mathrm{Ni} / \mathrm{Fe}^{\mathrm{III}}\right) \mathrm{O}_{5}\right]$ trigonal bipyramid and two $\left[\mathrm{PO}_{4}\right]$ tetrahedra. The $\left[\left(\mathrm{Ni} / \mathrm{Fe}^{\text {III }}\right) \mathrm{O}_{5}\right]$ polyhedron is linked with $\left[\mathrm{P1O}_{4}\right]$ tetrahedra into chains along [001] which additionally are aggregated by the linkage with $\left[\mathrm{P}_{2} \mathrm{O}_{4}\right]$ tetrahedra into a three-dimensional framework with composition $\left[\mathrm{Ni}_{0.78} \mathrm{Fe}_{3.19}\left(\mathrm{PO}_{4}\right)_{5}\right]^{3.84-}$ (Fig. 2).
The environment of the mixed $\left(\mathrm{Ni}^{\mathrm{II}} / \mathrm{Fe}^{\mathrm{III}}\right)$ site is defined by five oxygen atoms from four $\left[\mathrm{P} 2 \mathrm{O}_{4}\right]$ tetrahedra and one $\left[\mathrm{P} 1 \mathrm{O}_{4}\right]$ tetrahedron. The distances $(\mathrm{Ni} / \mathrm{Fe})-\mathrm{O}$ vary between 1.908 (3) and 1.979 (3) $\AA$. The average distance $((\mathrm{Ni} / \mathrm{Fe})$ $\mathrm{O})=1.937 \AA$ is slightly less than that in $\mathrm{K}_{4} \mathrm{MgFe}_{3}\left(\mathrm{PO}_{4}\right)_{5}(d((\mathrm{Mg} / \mathrm{Fe})-\mathrm{O})=1.952 \AA)$ (Hidouri et al., 2008). The tetrahedral orthophosphate anions deviate only slightly from ideal values with $\mathrm{P}-\mathrm{O}$ bond lengths ranging from 1.510 (3) to 1.542 (3) $\AA$.
The disordered $\mathrm{K}^{+}$cations are located in hexagonally-shaped channels running along [001], with occupancies of 0.73 (3) (K1A) and 0.23 (3) (K1B). The results of the construction of Voronoi-Dirichlet polyhedra (Blatov et al., 1995) show the K 1 A being surrounded by nine O atoms while K 1 B is surrounded by eight O atoms. The $\mathrm{K}-\mathrm{O}$ distances in the $\left[\mathrm{K}_{1} \mathrm{AO}_{9}\right]-$ polyhedron are in the range $2.719(5)-3.072(6) \AA$, while in the $\left[\mathrm{K}_{1 \mathrm{BO}_{8}}\right]$-polyhedron they are in the range 2.636 (13)3.065 (15) Å.

The main difference between the obtained solid solution and the phosphate $\mathrm{K}_{4} \mathrm{MgFe}_{3}\left(\mathrm{PO}_{4}\right)_{5}$ (Hidouri et al., 2008) is the splitting of the $\mathrm{K}^{+}$site in two positions. The occupation of the K1B site $(0.23(3))$ correlates with the increase of the iron content (from 3 to 3.19 ) in the starting matrix $\left[M^{\mathrm{II}} \mathrm{Fe}^{\mathrm{III}}{ }_{3}\left(\mathrm{PO}_{4}\right)_{5}\right]^{4-}$. It seems that a partial substitution of Ni by Fe in $\left[M^{\mathrm{II}} \mathrm{Fe}^{\mathrm{III}}{ }_{3}\left(\mathrm{PO}_{4}\right)_{5}\right]^{4-}$ causes the formation of vacancies in the cationic $\mathrm{K}^{+}$lattice and a splitting of the respective $\mathrm{K}^{+}$site. A similar influence of an heterovalent substitution on the splitting of alkaline metal sites was found for $\mathrm{KNi}_{0.93} \mathrm{Fe}^{\mathrm{II}}{ }_{0.07} \mathrm{Fe}^{\mathrm{III}}\left(\mathrm{PO}_{4}\right)_{2}$ (Strutynska et al., 2014).

## S2. Experimental

The title compound was obtained during investigation of the melting system $\mathrm{K}_{2} \mathrm{O}-\mathrm{P}_{2} \mathrm{O}_{5}-\mathrm{Fe}_{2} \mathrm{O}_{3}-\mathrm{NiO}-\mathrm{MoO}_{3}$. A mixture of $\mathrm{KPO}_{3}(14.16 \mathrm{~g}), \mathrm{NiO}(2.70 \mathrm{~g}), \mathrm{Fe}_{2} \mathrm{O}_{3}(2.88 \mathrm{~g})$ and $\mathrm{K}_{2} \mathrm{Mo}_{2} \mathrm{O}_{7}(4 \mathrm{~g})$ was ground in an agate mortar, placed in a platinum crucible and heated up to 1273 K . The melt was kept at this temperature for 3 h . After that, the temperature was cooled down to 873 K at a rate of $10 \mathrm{~K} / \mathrm{h}$. The crystals of (I) were separated from the remaining flux by boiling with water. The chemical composition of selected single-crystal was verified by EDX analysis. Analysis found (calculated) for $\mathrm{K}_{3.84} \mathrm{Ni}_{0.78} \mathrm{Fe}_{3.19}\left(\mathrm{PO}_{4}\right)_{5}$ in atomic percentage: K 17.62 (17.69), Ni 5.34 (5.39), Fe 20.83 (20.99), P 18.44 (18.24) and O 37.77 (37.69).

## S3. Refinement

Because of the similarity of possible coordination by O atoms, Ni and Fe were placed on the same site. Their coordinates and anisotropic displacement parameters (ADP) were constrained to be equal. The corresponding occupancy factors were refined using free variables. After that procedure, an unidentified high electron density peak was found near the position of the K site. It was supposed that this site can be occupied only by another $\mathrm{K}^{+}$caion. ADPs of both split K sites were constrained to be equal, while the occupancies were refined using free variables. The calculated occupancy factors of all partially occupied positions were close to those reported in this paper. To fix the electroneutrality of the compound, SUMP restraints in SHELXL (Sheldrick, 2008) were applied to the occupancy factors of the refined atoms.
The highest and lowest electron densities were found $1.00 \AA$ from O1 and $0.76 \AA$ from NI1, respectively.

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors $(\mathrm{gt})$ etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger.
