In the title salt,  $(C_2H_{10}N_2)_3[Pr_2(SO_4)_6] \cdot 6H_2O$ , the  $Pr^{III}$  cation is surrounded ninefold by five sulfate groups (two monodentate and three chelating) and by one water molecule [range of  $Pr-O$  bond lengths 2.383 (3) to 2.582 (3) Å]. The  $[Pr(SO_4)_5(H_2O)]$  groups are arranged in sheets parallel to (010). Two crystal water molecules and two ethylenediammonium cations (one with point group symmetry  $\bar{1}$ ) connect the sheets *via* O–H···O and N–H···O hydrogen bonds from weak up to medium strength into a three-dimensional framework structure.

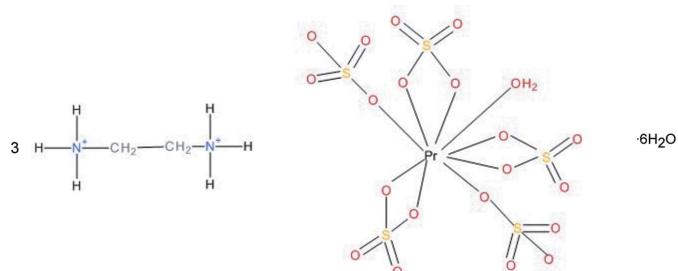

**Keywords:** crystal structure; praseodymium; ethylenediammonium; hydrogen bonds

**CCDC reference:** 1024418

**Supporting information:** this article has supporting information at journals.iucr.org/e

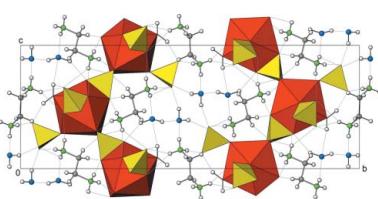

## 1. Chemical context

In the course of a systematic search for new ‘double salts’ of simple secondary amines and mono- or divalent cations of various inorganic acids, the structures of  $(C_2H_{10}N_2)[Li_2(SO_4)_2]$  and  $(C_2H_8N)[Cu(HSO_4)(SO_4)(H_2O)_4]$  have been described previously (Held, 2003, 2014). In continuation of these studies, lithium was replaced by trivalent praseodymium, yielding crystals of the title compound with composition  $(C_2H_{10}N_2)_3[Pr_2(SO_4)_6] \cdot 6H_2O$ .

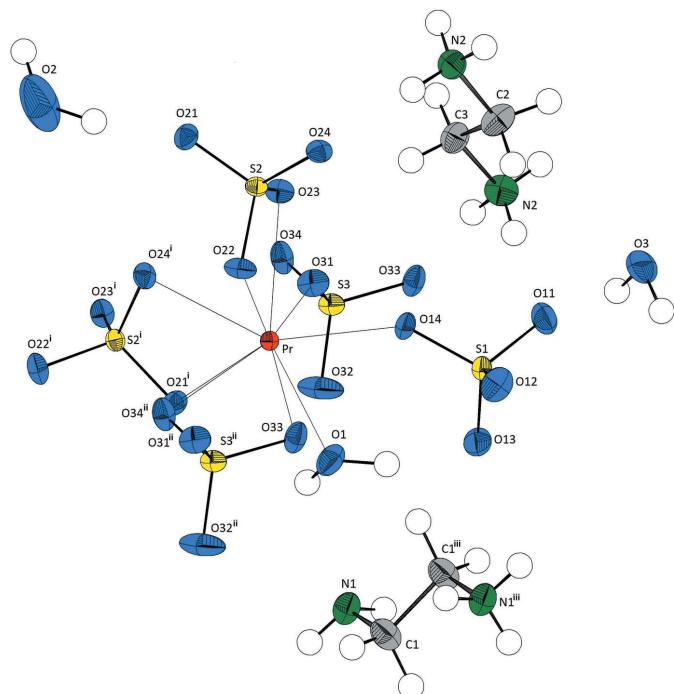

## 2. Structural commentary

The asymmetric unit of the title compound contains three  $(SO_4)^{2-}$  anions, one and a half  $[NH_2(CH_3)]^{2+}$  cations (the other half being generated by inversion symmetry), one  $Pr^{3+}$  cation as well as three water molecules (Fig. 1). The  $Pr^{3+}$  cation is surrounded by nine O atoms from five sulfate groups, two of which are monodentately bonding and three chelating, and of one water molecule. The averaged  $Pr-O$  distance in the resulting distorted monocapped square-antiprism,  $[Pr(SO_4)_5(H_2O)]$ , is 2.52 (7) Å. Praseodymium reaches an overall bond-valence sum (Brown & Altermatt, 1985) of 3.23 valence units. The S–O distances are nearly equal [average distance 1.479 (13) Å], however, the O–S–O angles vary [average bond angle 109.48 (2.05)°] clearly. One sulfate group (S2) interconnects two  $[PrO_9]$  polyhedra *via* two common edges parallel to [001], while another sulfate group (S3)

connects *via* a common edge and a common vertex parallel to [100], leading to the formation of sheets parallel to (010).

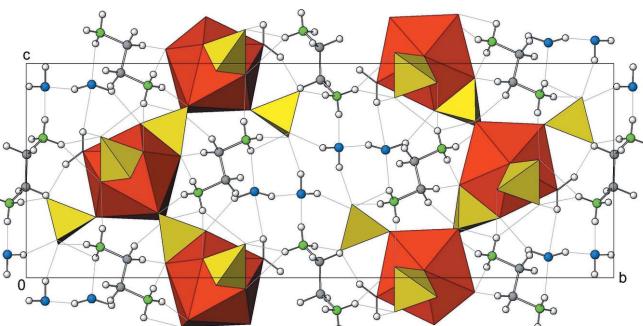

### 3. Supramolecular features

Hydrogen bonds of medium strength involving water molecules as donor groups and O atoms of the sulfate anions as acceptor groups interconnect neighbouring  $[\text{Pr}(\text{SO}_4)_5(\text{H}_2\text{O})]$  units. Together with relatively weaker N–H···O hydrogen bonds of the ammonium groups atoms to sulfate anions, a three-dimensional framework is formed (Table 1, Fig. 2).

**Figure 2**

(100)-projection of the crystal structure of the title compound. Hydrogen bonds are shown as light-grey dashed lines. Colour scheme: (SO<sub>4</sub>) tetrahedra (yellow), monocapped antiprism [PrO<sub>9</sub>] (red), O (blue), N (green), C (grey), H (white).

### 4. Synthesis and crystallization

The title compound was obtained by reaction of an aqueous solution of praseodymium(III) sulfate with ethylenediamine and sulfuric acid (18 mol/l) in a stoichiometric ratio 1:1:2. The title compound crystallized by slow evaporation of the solvent at room temperature in form of light-green crystals with dimensions up to 3 mm within a few weeks.

### 5. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. All H atoms were clearly

### Special details

**Experimental.** A suitable single-crystal was carefully selected under a polarizing microscope and mounted in a glass capillary. The scattering intensities were collected on an imaging plate diffractometer (*IPDS II*, Stoe & Cie) equipped with a fine focus sealed tube X-ray source ( $\text{Mo K}\alpha, \lambda = 0.71073 \text{ \AA}$ ) operating at 50 kV and 30 mA. Intensity data for the title compound were collected at room temperature by  $\omega$ -scans in 180 frames ( $0 < \omega < 180^\circ; \varphi = 0^\circ$  and  $90^\circ, \Delta\omega = 2^\circ$ , exposure time of 10 min) in the  $2\Theta$  range 2.29 to  $59.53^\circ$ . Structure solution and refinement were carried out using the programs *SIR97* (Altomare *et al.*, 1999) and *SHELXL97* (Sheldrick, 2008). The last cycles of refinement included atomic positions and anisotropic parameters for all atoms. The final difference maps were free of any chemically significant features. The refinement was based on  $F^2$  for ALL reflections.

**Geometry.** All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

**Refinement.** Refinement of  $F^2$  against ALL reflections. The weighted  $R$ -factor  $wR$  and goodness of fit  $S$  are based on  $F^2$ , conventional  $R$ -factors  $R$  are based on  $F$ , with  $F$  set to zero for negative  $F^2$ . The threshold expression of  $F^2 > \sigma(F^2)$  is used only for calculating  $R$ -factors(gt) *etc.* and is not relevant to the choice of reflections for refinement.  $R$ -factors based on  $F^2$  are statistically about twice as large as those based on  $F$ , and  $R$ -factors based on ALL data will be even larger.
