Received 29 August 2014; accepted 7 October 2014

Edited by S. V. Lindeman, Marquette University, USA

The title compound $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{O}_{2} \mathrm{~S}$, was identified as a product of diallylation of the meso-isomer of the corresponding norbornene sulfone, and it is an achiral compound. The fivemembered heterocycle adopts an envelope conformation with the $S$ atom deviating by 0.795 (3) $\AA$ from the other atoms of the ring (r.m.s. deviation $=0.0131$ ). Both allyl groups are antioriented relative to the S atom but their double bonds are directed in opposite directions relative to the plane of the heterocycle.

Keywords: crystal structure; allylation; norbonene derivatives; sulfones.

CCDC reference: 1027850

## S1. Comments

Alkylated sulfone derivatives have found useful application in the synthesis of $(E)-9,11$-dodecadien-l-y1 acetate, a sex pheromone of the red-bollworm moth (Bloch \& Abecassis, 1982). Moreover, sulfones (Bhat, 1994; Fielder et al., 2000; Nakayama et al., 1997) are latent diene (Fringuelli \& Taticchi, 1990) equivalents. In view of the applications of various alkyl and other functionalized sulfone derivatives (Bloch \& Abecassis, 1983; Bloch et al., 1983; Yamada et al., 1983), we have synthesized the title compound, $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{O}_{2} \mathrm{~S}$ (Figure 1), which is a non-chiral meso compound (i.e. internal recemate). The corresponding mono-allylated sulfone has been reported previously (Bloch et al., 1984). The starting sulfone was allylated with allyl bromide using $n$-BuLi as a base at $-75^{\circ} \mathrm{C}$ to room temperature for 25 h to furnish the desired di-allylated sulfone $\mathbf{1}$ in $80 \%$ yield along with the mono-allylated sulfone in $10 \%$ yield. After recrystallization from a mixture of hexane-dichloromethane (3:1), we obtained monoclinic crystals of the compound $\mathbf{1}$. The single-crystal X-ray study of the compound $\mathbf{1}$ clearly indicates that the di-allylation has been occurred at $\alpha, \alpha^{\prime}$-positions of the sulfone functionality with the allyl groups cis-positioned relatively to each other (see Figure 1). This stereoselectivity can be explained by stronger sterical hindrances at the endo face of the sulfone ring for the approaching electrophile (allyl bromide) as compared with those at its exo face. The title compound exhibits single bonds $\mathrm{Csp}^{3}-\mathrm{Csp}^{3}$ elongated up to 1.576 (3) $\AA$ [C4-C5]. The bond lengths C3-C4 of 1.559 (3) $\AA$ and C5-C6 of 1.568 (3) $\AA$ are also longer than that of the standard average Csp ${ }^{3}$ $\mathrm{Csp}^{3}$ single bond $[1.54 \AA$ ] (Chandrasekhar, 1992). The bond angle C3-C7-C6 of 94.14 (17) $\AA$ is contracted the most relative to the standard tetrahedral value of $109.5^{\circ}$. The angle $\mathrm{C} 13-\mathrm{C} 14-\mathrm{C} 15$ is found to be the most expanded one at 125.1 (2) ${ }^{\circ}$. The five-membered heterocycle has an envelope conformation, in which four C atoms are in the same plane (C8-C5-C4-C12) and $\mathrm{SO}_{2}$ group deviates from it. Two allylic double bonds are oriented in opposite direction to each other. Previously, Pool and White (2000) have also reported that the average lengths of $\mathrm{C}-\mathrm{C}$ bonds corresponding to C 3 - C4 and C5-C6 in our structure in the similar bicyclic cyclohexene derivatives are also significantly longer (by 0.02 $\AA$ ) than the corresponding $\mathrm{C}-\mathrm{C}$ bond distances for the saturated bicyclic cyclohexane derivatives. Later, Birney and coworkers (Birney et al., 2002) have studied the X-ray crystal data of bicyclo[2.2.1]moiety containing compounds in order to estimate their retro-Diels-Alder reactivity.

## S2. Experimental Section

Melting points were recorded on Veego melting point apparatus and are uncorrected. Nuclear Magnetic Resonance (NMR) spectra were recorded on a Bruker (Avance $\mathrm{III}^{\mathrm{TM}} 500$ ) spectrometer operated at 500 MHz for ${ }^{1} \mathrm{H}$ and 125.7 MHz for ${ }^{13} \mathrm{C}$ nuclei. The high-resolution mass spectrometric (HRMS) measurements were carried out using Bruker (Maxis Impact) instrument. Infrared (IR) spectrum of solid sample was recorded as KBr pellets on Nicolet Impact-400 FT IR spectrometer.

## S2.1. Synthesis and Crystallization of Compound_1

The solution of the precursor sulfone ( $600 \mathrm{mg}, 3.26 \mathrm{mmol}$ ) in anhydrous THF ( 15 mL ) was cooled to $-75^{\circ} \mathrm{C}$ under nitrogen $\left(\mathrm{N}_{2}\right)$. To this solution, $n-\operatorname{BuLi}(4.90 \mathrm{~mL}, 2.4$ equiv, 1.6 M solution in hexanes) was added in dropwise manner and the reaction mixture was stirred for 30 min . Later, allyl bromide ( $0.83 \mathrm{~mL}, 9.77 \mathrm{mmol}$ ) was added slowly and the stirring continued at the same temperature for 2 h . Then, the reaction mixture was allowed to raise to the room temperature and the stirring continued for 22 h more. At the conclusion of the reaction (TLC monitoring), the reaction mixture was quenched with water ( 5 mL ) and the solvent was removed under reduced pressure. Then, the resulting residue was extracted with diethyl ether ( $3 \times 30 \mathrm{~mL}$ ). The combined organic layers were washed with brine ( $2 \times 20 \mathrm{~mL}$ ) and dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The solvent was removed under reduced pressure and the crude product was purified by silica gel column chromatography using ethyl acetate-petroleum ether (1:9) as an eluent to afford the di-allylated sulfone $\mathbf{1}$ ( 690 $\mathrm{mg}, 80 \%)$ as a white crystalline solid. A further elution with ethyl acetate-petroleum ether ( $2: 8$ ) delivered the previously known mono-allylated sulfone ( $75.40 \mathrm{mg}, 10 \%$ ) as a pale yellow liquid. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopic data of the monoallylated sulfone was compared with the literature report (Bloch et al., 1984) and found to be identical. After purification the title compound was recrystallized from a mixture of hexane-dichloromethane (3:1) by slow evaporation to get the colourless crystals. $R_{f}=0.91$ ( $20 \%$ ethyl acetate in petroleum ether); mp: $348.15-349.15 \mathrm{~K} .{ }^{1} \mathrm{H} \mathrm{NMR}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$ : $\delta(\mathrm{ppm})=6.20(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 5.88-5.80(\mathrm{~m}, 2 \mathrm{H}), 5.23(\mathrm{dd}, J=16.9,1.2 \mathrm{~Hz}, 2 \mathrm{H}), 5.16(\mathrm{~d}, J=10.0 \mathrm{~Hz}, 2 \mathrm{H}), 2.99(\mathrm{br} \mathrm{s}, 2 \mathrm{H})$, $2.77-2.72(\mathrm{~m}, 2 \mathrm{H}), 2.45-2.40(\mathrm{~m}, 2 \mathrm{H}), 2.37-2.30(\mathrm{~m}, 4 \mathrm{H}), 1.67(\mathrm{~d}, J=8.8 \mathrm{~Hz}, 1 \mathrm{H}), 1.39(\mathrm{~d}, J=8.8 \mathrm{~Hz}, 1 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\left(125.7 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})=136.9,133.6,118.6,62.5,49.8,45.6,45.3,30.8$; HRMS (ESI, Q-ToF) $m / z$ : calculated for $\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{NaO}_{2} \mathrm{~S}[\mathrm{M}+\mathrm{Na}]^{+}$287.1076, found: 287.1077; IR (neat): $v_{\text {max }}=3021,2978,1640,1443,1306,1216,1123 \mathrm{~cm}^{-1}$.

## S2.2. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. All H atoms were placed in their geometrically calculated positions and refined using a riding model with $\mathrm{C}-\mathrm{H}$ distances of $0.95 \AA$ for all H atoms bound to $s p^{2} \mathrm{C}$ atoms and $1.00 \AA$ for all others. $\mathrm{U}_{\mathrm{iso}}(\mathrm{H})=x \mathrm{U}_{\mathrm{eq}}(\mathrm{C})$, where $x=1.5$ for allylic methylidene $\left[=\mathrm{C}(11,15) \mathrm{H}_{2}\right] \mathrm{H}$ atoms and 1.2 for all other H atoms. The positions of allylic methylidene and non-allylic methine $[=\mathrm{C}(1,2) \mathrm{H}-] \mathrm{H}$ atoms were calculated using the SHELXL-97 instructions AFIX 93 and AFIX 43 respectively (Sheldrick, 2008).

Primary atom site location: structure-invariant direct methods

Secondary atom site location: difference Fourier map
Hydrogen site location: inferred from neighbouring sites
H -atom parameters constrained
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}^{2}\right)+(0.0388 P)^{2}+1.1426 P\right]$ where $P=\left(F_{\mathrm{o}}^{2}+2 F_{\mathrm{c}}^{2}\right) / 3$
$(\Delta / \sigma)_{\max }<0.001$
$\Delta \rho_{\text {max }}=0.46$ e $\AA^{-3}$
$\Delta \rho_{\text {min }}=-0.45$ e $\AA^{-3}$

## Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.
Refinement. Refinement of $F^{2}$ against ALL reflections. The weighted $R$-factor $w R$ and goodness of fit $S$ are based on $F^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>\sigma\left(F^{2}\right)$ is used only for calculating $R$-factors (gt) etc. and is not relevant to the choice of reflections for refinement. $R$-factors based on $F^{2}$ are statistically about twice as large as those based on $F$, and $R$ - factors based on ALL data will be even larger. All nonhydrogen atoms are refined anisotropically and all hydrogen atoms are refined using riding model.
