The reaction of bis(anthracene)cobaltate(−I) with excess cycloheptatriene, C<sub>7</sub>H<sub>8</sub>, resulted in a new 18-electron cobaltate containing two different seven-membered ring ligands, based on single-crystal X-ray diffraction. The asymmetric unit of this structure contains two independent cation–anion pairs of the title complex, [K(18-crown-6)][Co( $\eta^3$ -C<sub>7</sub>H<sub>7</sub>)( $\eta^5$ -C<sub>7</sub>H<sub>9</sub>)], where 18-crown-6 stands for 1,4,7,10,13,16-hexaoxacyclooctadecane (C<sub>12</sub>H<sub>24</sub>O<sub>6</sub>), in general positions and well separated. Each (18-crown-6)potassium cation is in contact with the  $\eta^3$ -coordinating ligand of one cobaltate complex. Each  $\eta^3$ -coordinating ligand behaves as an allylic anion whose *exo*-diene moiety is bent away from the allylic plane, and thus is not involved directly in the bonding. The metal-coordinating portions of the anionic  $\eta^5$  ligands are planar and one of these ligands is modeled as disordered over two positions, with occupancy ratio 0.699 (5):0.301 (5), such that one orientation is rotated by one carbon atom with respect to the other. The diffraction intensities were integrated according to non-merohedral twin law [ $\bar{1}$  0 0/0  $\bar{1}$  0/0.064 0 1], a 180° rotation about reciprocal lattice axis [001], and the masses of the twin domains refined to equal amounts. As both ligands are formally coordinated as anions, the cobalt atom is best considered to be Co<sup>I</sup>. This compound is of interest as the first to possess cycloheptatrienyl and cycloheptadienyl ligands in an anionic metal complex.

## 1. Chemical context

To date there is only one crystal structure reported of a homoleptic cycloheptatriene (CHT) transition metal complex, Zr( $\eta^6$ -C<sub>7</sub>H<sub>8</sub>)<sub>2</sub> (Green & Walker, 1989), presumably because such molecules tend to isomerize. In the case of this zirconium species, room-temperature syntheses produced a mixture of it and its hydrogen-migrated isomer Zr( $\eta^7$ -C<sub>7</sub>H<sub>7</sub>)( $\eta^5$ -C<sub>7</sub>H<sub>9</sub>). For the titanium analog, although the homoleptic CHT complex was initially observed by NMR, no crystals were obtained, and it readily isomerized. Metal vapor co-condensation reactions of titanium and iron with CHT also led to the isomerized forms (Timms & Turney, 1976; Blackborow *et al.*, 1976). Co-condensation of molybdenum atoms with CHT resulted in Mo( $\eta^6$ -C<sub>7</sub>H<sub>8</sub>)<sub>2</sub>, which could be isolated at room temperature, but was observed to isomerize to Mo( $\eta^7$ -C<sub>7</sub>H<sub>7</sub>)( $\eta^5$ -C<sub>7</sub>H<sub>9</sub>) with a half-life of *ca* 200 h (Green *et al.*, 1989).

Given the tendency for homoleptic CHT complexes to isomerize, we decided to investigate whether this would occur in the late transition metal low-valent cobalt system. The 18-electron anionic precursor bis(anthracene)cobaltate(−I) was chosen because it had been demonstrated that the anthracene ligands are quite labile (Brennessel *et al.*, 2002; Brennessel & Ellis, 2012). Under an argon atmosphere, excess CHT was

introduced dropwise to a cold tetrahydrofuran solution of bis(anthracene)cobaltate(−I). Red–brown single crystals of the isolated product suitable for an X-ray diffraction experiment revealed a new 18-electron cobalt complex anion containing two different cyclic ligands,  $[\text{Co}(\eta^3\text{-C}_7\text{H}_7)(\eta^5\text{-C}_7\text{H}_9)]^-$ , which confirmed that isomerization had occurred and that both anthracene ligands had been displaced. As no spectroscopy had been performed, it is unknown if an anionic intermediate like  $[\text{Co}(\eta\text{-C}_7\text{H}_8)_2]^-$  was initially formed, and if formed, whether it had any lifetime in cold and/or room-temperature solutions.

## 2. Structural commentary

There are two independent contact ion pairs of  $[\text{K}(18\text{-crown-6})][\text{Co}(\eta^3\text{-C}_7\text{H}_7)(\eta^5\text{-C}_7\text{H}_9)]$ , (I), in the asymmetric unit (Figs. 1 and 2). The potassium cations are complexed by 18-crown-6 cyclic ethers and are in contact with carbon atoms of the  $\eta^3$ -coordinating ligands of the cobalt anions, with  $\text{K}\cdots\text{C}$  distances ranging from 3.207 (3) to 3.538 (4) Å. The longest  $\text{K}\cdots\text{C}$  distance is well within the sum of the van der Waals radii for potassium and carbon of 4.45 Å (Bondi, 1964). The  $\text{C}_7\text{H}_7$  ligands are bonded  $\eta^3$  to the cobalt atoms, and their  $\text{Co}-\text{C}$  and  $\text{C}=\text{C}$  bond lengths are consistent with their formulations as anionic allylic ligands with *exo*-diene moieties, *i.e.*,  $\eta^3$ -cycloheptatrienyl ligands (see Table 1). Especially noteworthy are the lengths of the double bonds in the *exo*-diene portions, which are normal for  $\text{C}=\text{C}$  bonds and show that the *exo*-diene moieties are independent of the allylic coordination to the metal centers. The  $\text{Co}-\text{C}$  bond lengths have the typical long–short–long pattern seen in other  $\eta^3$ -cycloheptatrienyl transition metal species (Table 2), and the *exo*-diene portions of these ligands are essentially planar and are bent away from the plane of the allylic regions by 28.0 (4) and 27.2 (4)°, for anions containing Co1 and Co2, respectively. Interestingly, the

Figure 1

Structure of the first independent molecule of (I), with displacement ellipsoids shown at the 50% probability level. H atoms have been omitted. Thin lines indicate the primarily electrostatic interactions between the  $\text{K}^+$  cation and the crown ether and  $\eta^3$  ring.

Figure 2

Structure of the second independent molecule of (I), with displacement ellipsoids shown at the 50% probability level. H atoms and the minor component of the disordered ring have been omitted. Thin lines indicate the primarily electrostatic interactions between the  $\text{K}^+$  cation and the crown ether and  $\eta^3$  ring.

tropylium cation ( $\text{C}_7\text{H}_7^+$ ) also has the formula  $\text{C}_7\text{H}_7$ ; however, tropylium as a ligand is aromatic, and thus planar and with similar  $\text{C}=\text{C}$  bond lengths. The  $\eta^5$ -coordinating ligands are essentially planar in their cobalt-bonded regions with r.m.s. deviations from planarity of 0.050 and 0.051 Å for planes C8–C12 and C22–C26, respectively (see Figs. 1 and 2).

With cobalt bound to three ('allyl') and five ('pentadienyl') carbon atoms of the seven-membered rings as described above, it is thought best to consider the cobalt atom as formally  $\text{Co}^1$  with two anionic ligands. Extended Hückel MO

calculations on  $[\text{Fe}(\eta^3\text{-C}_7\text{H}_7)(\text{CO})_3]^-$  (Hofmann, 1978), whose structure has been reported (Sepp *et al.*, 1978), not only demonstrated that there is a preference for the metal to bind through the  $\eta^3$ -allylic region of the ligand rather than through the diene segment, but showed that there is more charge localization on the ring for the former conformation over the latter.

The exact mechanism of isomerization has not been determined for (I), including whether the hydrogen transfer is intra- or intermolecular. In one DFT study on selected early transition metal complexes, the mechanism for hydrogen migration was determined to be intramolecular, and a metal hydride intermediate was predicted to be favored over a direct ligand-to-ligand transfer (Herbert *et al.*, 2004). The same conclusion was reached in kinetic studies on similar molybdenum complexes (Green *et al.*, 1989). If these studies can be extended to the cobalt system, then it could be proposed that the hydrogen migration occurs *via* a  $[\text{CoH}(\eta\text{-C}_7\text{H}_7)(\eta\text{-C}_7\text{H}_8)]^-$  intermediate.

### 3. Database survey

As mentioned above, there is exactly one homoleptic CHT structure in the Cambridge Structural Database to date (CSD, Version 5.36, update No. 1, November 2014; Groom & Allen, 2014), namely  $\text{Zr}(\eta^6\text{-C}_7\text{H}_8)_2$  (Green & Walker, 1989). All others have been structurally characterized after isomerization, including (I). There are 23 structures containing an  $\eta^5$ -cycloheptadienyl ligand, but only 12 structures containing an  $\eta^3$ -cycloheptatrienyl ligand bonded to a single metal atom. Of

**Table 2**

Comparison of bond lengths (Å) and fold angles (°) for selected later transition metal complexes containing  $\eta^3$ -cycloheptatrienyl ligands, with numbering according to Fig. 3. Fold angles are defined as the angles between the C1–C2–C3 (allylic) and C1–C3–C4–C5–C6–C7 (*exo*-diene) mean planes.

the latter, just three are anionic; they are of the form  $[\text{AsPh}_4][\text{M}(\text{CO})_3(\eta^3\text{-C}_7\text{H}_7)]$ ,  $M = \text{Fe}$  (Sepp *et al.*, 1978) and  $M = \text{Ru}, \text{Os}$  (Astley *et al.*, 1990). (I) is the first example of an anionic transition metal complex containing both cycloheptadienyl and cycloheptatrienyl ligands to be reported.

### 4. Synthesis and crystallization

All operations were performed under an atmosphere of 99.5% argon further purified by passage through columns of activated BASF catalyst and molecular sieves. Standard Schlenk techniques were employed for all reactions with a double manifold vacuum (0.01 Torr) line. Solutions were transferred *via* stainless steel double-ended needles (cannulas) and glass-covered magnetic stir bars were employed. Cycloheptatriene was distilled from Na/K alloy.

Excess cycloheptatriene was added dropwise to a deep pinkish-red solution of  $[\text{K}(18\text{-crown-6})(\text{THF})_2][\text{Co}(\eta^4\text{-C}_{14}\text{H}_{10})_2]$  (0.500 g, 0.579 mmol; Brennessel *et al.*, 2002; Brennessel & Ellis, 2012) in THF (50 ml, 195 K). The solution was slowly warmed to room temperature, at which point it was deep yellowish brown. After the solvent was removed *in vacuo* and heptane (70 ml) was added, the slurry was filtered. The product was washed with pentane (20 ml) and dried *in vacuo*, yielding a blackish-gray solid [0.292 g, 92%, based on cobalt

**Figure 4**  
View of the ring ligand disorder. Displacement ellipsoids are shown at the 50% probability level and H atoms have been omitted. The numbering scheme of the minor component of the disorder was chosen to show the mirror-like symmetry that allows both orientations to fit within essentially the same volume.

and using the formulation of (I)]. This product was only characterized by single-crystal X-ray diffraction. Red–brown blocks were grown from a pentane-layered THF solution at 273 K.

## 5. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 3. The refinement stalled at  $R_1 = 0.19$ , at which point the structure was examined for twinning (Parsons *et al.*, 2003). Non-merohedral twinning was identified and the data were re-integrated accordingly. Application of twin law  $[\bar{1} 0 0 / 0 \bar{1} 0 / 0.064 0 1]$ , a  $180^\circ$  rotation about reciprocal lattice direction  $[001]$ , reduced the  $R_1$  residual to its final value of 0.043 (Table 3). The mass ratio of the twin components refined to 0.5040 (7):0.4960 (7).

The  $\eta^5$ -coordinating ligand C8–C14 is modeled as disordered over two positions with site occupancy ratio 0.699 (5):0.301 (5), such that the ethyl linkage is shifted by one carbon atom (see Fig. 4). Analogous bond lengths and angles between the two positions of the disordered ring were heavily restrained to be similar. Anisotropic displacement parameters for pairs of proximal atoms from the two components of the disorder were constrained to be equivalent (Sheldrick, 2015).

H-atom positions of ring-ligand carbon atoms, except those in the minor component of the disorder, were located in a difference map and refined freely. All other H atoms were placed geometrically and treated as riding atoms: methine and  $sp^2$ , C–H = 1.00 Å, and methylene, C–H = 0.99 Å, with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ .

728 parameters

45 restraints

Primary atom site location: structure-invariant  
direct methods

Secondary atom site location: difference Fourier  
map

Hydrogen site location: mixed

H atoms treated by a mixture of independent  
and constrained refinement

$w = 1/[\sigma^2(F_o^2) + (0.0271P)^2 + 2.3296P]$

where  $P = (F_o^2 + 2F_c^2)/3$

$(\Delta/\sigma)_{\max} = 0.001$

$\Delta\rho_{\max} = 0.46$  e Å<sup>-3</sup>

$\Delta\rho_{\min} = -0.47$  e Å<sup>-3</sup>

*Special details*

**Refinement.** The structure was integrated and refined as a non-merohedral twin (Parsons *et al.*, 2003). Application of twin law  $[-1\ 0\ 0 / 0\ -1\ 0 / 0.064\ 0\ 1]$ , a  $180^\circ$  rotation about reciprocal lattice  $[001]$ , reduced the  $R$  residual from 19.0% to its final value of 4.3%. The mass ratio of the twin components refined to 0.5039 (7):0.4961 (7).

The  $\eta^5$ -coordinating ligand C8—C14 is modeled as disordered over two positions, 0.697 (5):0.303 (5), such that the ethyl linkage is shifted by one carbon atom. Analogous bond lengths and angles between the two positions of the disordered ring were heavily restrained to be similar. Anisotropic displacement parameters for pairs of proximal atoms from the two components of the disorder were constrained to be equivalent.

H atom positions of ring-ligand carbon atoms, except those in the minor component of the disorder, were refined freely. All other H atoms were placed geometrically and treated as riding atoms: methine and  $sp^2$ , C—H = 1.00 Å, and methylene, C—H = 0.99 Å, with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ .

*Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters ( $\text{\AA}^2$ )*
