The title compound, [CrCu(C₅H₁₁NO₂)(C₅H₁₂NO₂)(NCS)₂(H₂O)] or [Cr(μ -mdea)Cu(μ -Hmdea)(NCS)₂H₂O], (where mdeaH₂ is *N*-methyleneethanolamine, C₅H₁₃NO₂) is formed as a neutral heterometal Cu^{II}/Cr^{III} complex. The molecular structure of the complex is based on a binuclear {CuCr(μ -O)₂} core. The coordination environment of each metal atom involves the *N*,*O*,*O* atoms of the tridentate ligand, one bridging O atom of the ligand and the N atom of the thiocyanato ligands. The Cu^{II} ion adopts a distorted square-pyramidal coordination while the Cr^{III} ion has a distorted octahedral coordination geometry completed by the aqua ligand. In the crystal, the binuclear complexes are linked via two pairs of O—H \cdots O hydrogen bonds to form inversion dimers, which are arranged in columns parallel to the *a* axis. In the μ -mdea ligand two —CH₂ groups and the methyl group were refined as disordered over two sets of sites with equal occupancies. The structure was refined as a two-component twin with a twin scale factor of 0.242 (1).

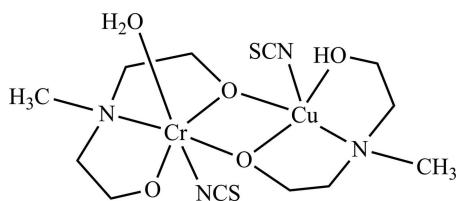

1. Chemical context

The search for heterometallic complexes has been stimulated by the general interest in combining different metal atoms within one assembly, since even the synthesis of such complexes often represents a non-trivial task. In addition, it was found that such compounds are potential novel magnetic materials (Gheorghe *et al.*, 2010; Long *et al.*, 2010; Visinescu *et al.*, 2009; Amiri *et al.*, 2010; Timco *et al.*, 2008). Polydentate alkoxido ligands possessing versatile bridging modes were recognized as promising reagents for the synthesis of new heterometallic complexes. In particular diethanolamine and its *N*-alkyl derivatives are recognized *N*,*O* ligands that possess an interesting coordination chemistry and are thus often used for the design of various multimetallic cores and polymeric assemblies (Allen, 2002; Singh & Mehrotra, 2004; Verkade, 1993; Stamatatos *et al.*, 2008; Beedle *et al.*, 2008; Kirillov *et al.*, 2008). Great interest in the synthesis and investigation of polynuclear chromium containing compounds dates from the late 90s, mostly due to the works of Winpenny and co-workers devoted to magnetic studies of high-nuclear cages and wheels (McInnes *et al.*, 2005; Affronte *et al.*, 2005). As has been shown in our previous publications, the synthetic approach named ‘direct synthesis of coordination compounds’ [Pryma *et al.*, 2003; Nesterov *et al.*, 2011, 2012; Nesterova (Pryma) *et al.*, 2004; Nesterova *et al.* 2005; Buvaylo *et al.*, 2005] is an efficient method to obtain novel heterobi- (Buvaylo *et al.*, 2005),

OPEN ACCESS

heterotrimetallic (Nesterov *et al.*, 2011), polymeric [Nesterova (Pryma) *et al.*, 2004; Nesterova *et al.*, 2005, 2008] and polynuclear (Nesterov *et al.*, 2012) complexes. In a continuation of our investigations in the field of the ammonium salt route for direct synthesis (Pryma *et al.*, 2003; Nikitina *et al.*, 2008) the title compound $[\text{Cr}(\mu\text{-mdea})\text{Cu}(\mu\text{-Hmdea})(\text{NCS})_2\text{H}_2\text{O}]$ (where mdeaH₂ is *N*-methylmethanolamine) was prepared using copper powder, Reineckes salt, ammonium thiocyanate and a non-aqueous solution of mdeaH₂ in air.

2. Structural commentary

The molecular structure of the title complex (Fig. 1) is based on a binuclear $\{\text{CuCr}(\mu\text{-O})_2\}$ core. Each ligand (protonated and deprotonated) displays tridentate coordination by N and O atoms to a specific metal atom as well by a bridging O atom to the neighbouring metal atom. Thus the Cu^{II} ion is pentacoordinated by the μ -oxygen (O1, O3) atoms of the protonated and deprotonated ligands, the N3 amino nitrogen atom of the mdea ligand and atom N1 of the thiocyanato ligand in the basal plane, and by the remaining oxygen atom (O4) of the Hmdea ligand in the apical site, and displays a distorted square-pyramidal coordination geometry. The apical oxygen atom is bound through the Cu1–O4 [2.259 (4) Å] bond, which is typically elongated in comparison to those in basal sites, *i.e.* Cu1–O1 [1.994 (3) Å] and Cu1–O3 [1.909 (4) Å]. The coordination environment of the Cr^{III} atom is completed in a distorted octahedral geometry by the additional coordination of atom O5 of the water molecule in an axial position *trans* to the N4 amino nitrogen atom of the ligand. The Cr–(O,N) bond lengths are within the range 1.912 (4)–2.118 (5) Å.

The binding of each *mdea* ligand involves two five-membered *M*–N–C–C–O chelate rings (*M* = Cu, Cr). The

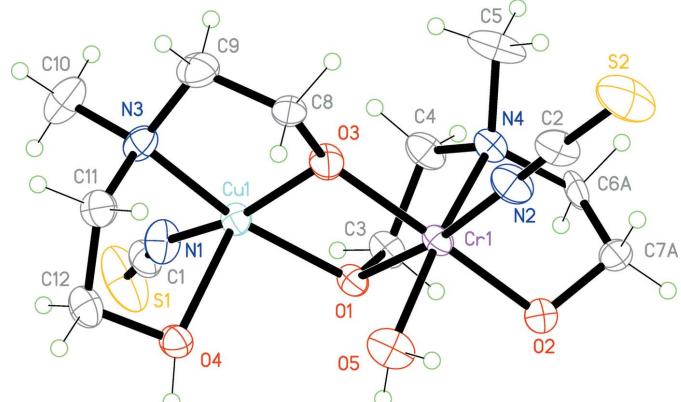

Figure 1

The molecular structure of the title complex with 30% probability displacement ellipsoids

Table 1
Hydrogen-bond geometry (Å, °).

D–H···A	D–H	H···A	D···A	D–H···A
O4–H4···O2 ⁱ	0.86	1.86	2.595 (7)	142
O5–H5B···O1 ⁱ	0.86	2.18	3.014 (7)	162

Symmetry code: (i) $-x, -y, -z$.

angles N3–Cu1–O4 and N3–Cu1–O3 are 82.2 (2) and 84.0 (2)° respectively. The analogous N4–Cr1–O1 and N4–Cr1–O2 angles are 84.2 (2) and 82.9 (2)°, respectively.

The Cu1–O1–Cr1–O3 core is non-planar, and has both atoms O1 and O3 shifted opposite to the direction of apical oxygen O5 atom of the water molecule. In this core, the Cu1···Cr1 separation is 2.998 (1) Å. The representative Cu1–O1–Cr1 and Cu1–O3–Cr1 bond angles are 97.8 (1) and 101.5 (2)° respectively, while the O1–Cr1–O3 and O1–Cu1–O3 bond angles are 78.6 (2) and 79.6 (1)°. The dihedral angle between two Cu–O–Cr planes is 18.49 (15)°.

In general, all bonding parameters and the dimensions of the angles in the title complex are in good agreement with those encountered in related aminoalcohol complexes (Figiel *et al.*, 2010; Kirillov *et al.*, 2008; Gruenwald *et al.*, 2009; Vinogradova *et al.*, 2002).

3. Supramolecular features

In the crystal, the binuclear complexes are linked via two pairs of O–H···O hydrogen bonds (Table 1) to form inversion dimers (Fig. 2), which are arranged in columns parallel to the *a* axis (Fig. 3).

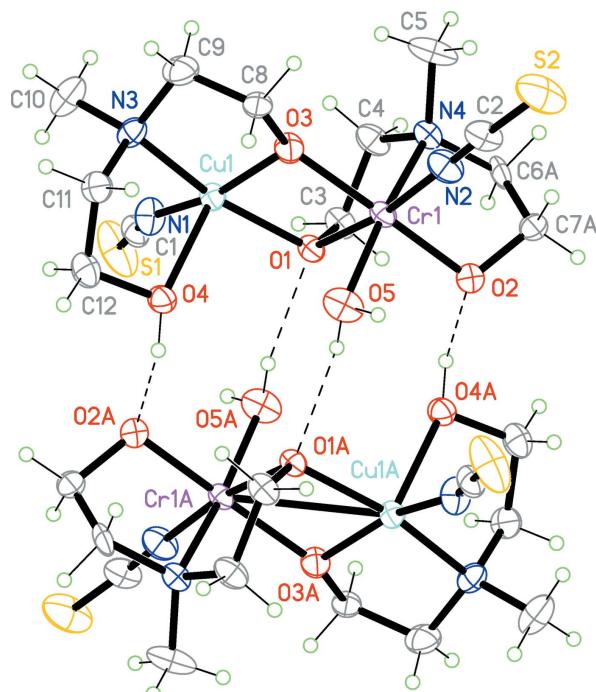

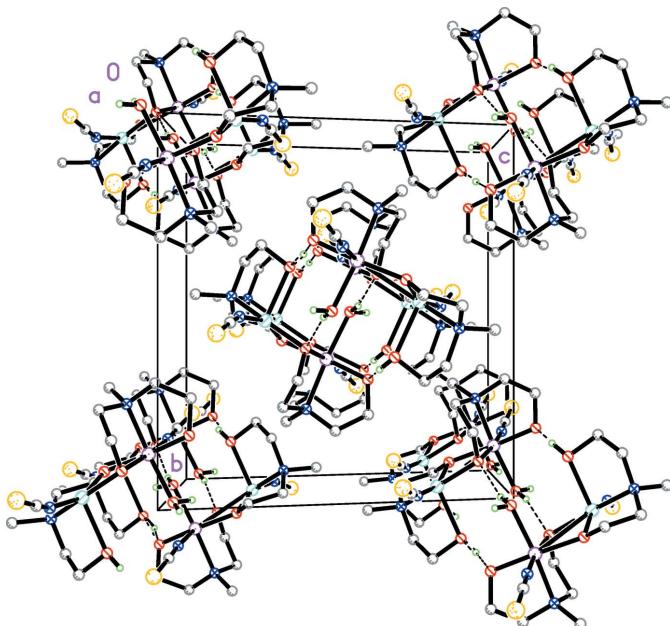

Figure 2

An inversion dimer of title compound connected via two pairs of O–H···O hydrogen bonds (dashed lines). [Symmetry code: (A) $-x, -y, -z$.]

**Figure 3**

Crystal packing of the title compound viewed along the a axis.

4. Database survey

A search of the Cambridge Structural Database (Version 5.36; last update February 2015; Groom & Allen, 2014) for related complexes with *N*-methyldiethanolamine gave 109 hits. Therein closely related structures with a metal–O–metal–O core are heteronuclear complexes with Cu (Figiel *et al.*, 2010), Ga (Pugh *et al.*, 2012) and heterometallic with Zn, Co and Cu (Nesterov *et al.*, 2011).

5. Synthesis and crystallization

Copper powder (0.079 g, 1.25 mmol), $\text{NH}_4[\text{Cr}(\text{NCS})_4(\text{NH}_3)_2]\cdot\text{H}_2\text{O}$ (0.443 g, 1.25 mmol), NH_4SCN (0.095 g, 1.25 mmol), *N*-methyldiethanolamine (1.3 ml, 1.25 mmol) and methanol (20 ml) were heated in air at 323–333 K and stirred magnetically for 30 min. Deep-blue crystals suitable for crystallographic study were formed by slow evaporation of the resulting solution in air. The crystals were filtered off, washed with dry isopropanol and finally dried *in vacuo* at room temperature. Yield: 0.11 g, 17.7%.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. Hydrogen atoms were located in difference Fourier maps and refined in a riding-model approximation with $U_{\text{iso}} = nU_{\text{eq}}$ of the carrier atom ($n = 1.5$ for methyl group and $n = 1.2$ for other hydrogen atoms). Atoms C5, C6 and C7 were refined as disordered over two sets of sites with equal occupancies. The structure was refined as a two-component twin with a twin scale factor of 0.242 (1).

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refined as a 2-component twin.
