**Keywords:** crystal structure; five-coordinate copper(II) complex; Atom Transfer Radical Addition (ATRA); ligand disorder.

**CCDC reference:** 1478413

**Supporting information:** this article has supporting information at journals.iucr.org/e

In the asymmetric unit of the title compound,  $[\text{CuBr}(\text{C}_{18}\text{H}_{18}\text{N}_4)]\text{Br}$ , there are three crystallographically independent cations. One of the cations exhibits positional disorder of the pyridin-2-ylmethyl groups over two sets of sites with refined occupancies of 0.672 (8) and 0.328 (8). The outer-sphere bromine counter-ion is severely disordered over multiple sites. In each cation, the  $\text{Cu}^{\text{II}}$  ion is coordinated by the four N atoms of the tris(pyridin-2-ylmethyl)amine ligand and one bromine and adopts a slightly distorted trigonal-bipyramidal geometry.

## 1. Chemical context

Atom Transfer Radical Addition (ATRA) reactions involve the formation of carbon–carbon bonds through the addition of saturated poly-halogenated hydrocarbons to alkenes (Eckenhoff & Pintauer, 2010). First reported by Kharasch in the 1940s (Kharasch *et al.*, 1945), the reaction incorporates halogen-group functionalities within products which can be used as starting reagents in further functionalization reactions (Iqbal *et al.*, 1994). Subsequently, ATRA reactions have emerged as some of the most atom-economical methods for simultaneously forming C–C and C–X bonds, leading to the production of more attractive molecules (Eckenhoff & Pintauer, 2010). Most ATRA reactions proceed in the presence of a free-radical precursor or transition metal complex (catalyst), as the halogen-atom transfer agent and have been efficiently catalyzed by complexes incorporating nickel, ruthenium, iron, and copper (Eckenhoff *et al.*, 2008). Studies suggest that the type of ligands used in ATRA reactions significantly influence the behavior of the catalyst generated due to different steric and electronic interactions with the metal atom (Matyjaszewski *et al.*, 2001). Copper complexes made with tetradentate nitrogen-based ligands such as tris[2-(dimethylamino)ethyl]amine ( $\text{Me}_6\text{TREN}$ ), 1,4,8,11-tetraaza-1,4,8,11-tetramethylcyclotetradecane ( $\text{Me}_6\text{CYCLAM}$ ), and tris(pyridin-2-ylmethyl)amine (TPMA) are currently some of the most active multi-dentate ligand structures used in atom-transfer radical reactions (Tang *et al.*, 2008). Given the significance and application of complexes made from these tetradentate ligands, we report on the synthesis and crystal structure of the title compound  $[\text{CuBr}(\text{C}_{18}\text{H}_{18}\text{N}_4)]\text{Br}$  (I) which incorporates tris(pyridin-2-ylmethyl)amine.

## 2. Structural commentary

There are three crystallographically independent copper(II) atoms within the asymmetric unit reported herein (Fig. 1). Each of the atoms adopts a slightly distorted trigonal-bipyramidal geometry and is coordinated by the four nitrogen atoms of the tris(pyridin-2-ylmethyl)amine ligand and one bromine atom (Table 1). The amine nitrogen and bromine atoms adopt the apical positions of the coordination environment and the pyridine nitrogen atoms are located in the equatorial plane. Derived metrics (bond lengths and angles) from the copper atoms to their respective coordinating atoms are typical (*MOGUL* analysis; Bruno *et al.*, 2004). The  $\tau$ -5 values for Cu1, Cu2 and Cu3 are 0.99, 0.99 and 0.89, respectively (Addison *et al.*, 1984); the latter deviates the most from ideal geometry due to the disorder present in that molecule.

One of the three independent cations exhibits positional disorder of the pyridin-2-ylmethyl groups (see *Refinement* below for specific details). Despite this disorder, the connect-

tivity is unequivocal. Unlike the polymorphic structure (Eckenhoff *et al.*, 2008) that has crystallographically imposed symmetry on the pyridin-2-ylmethyl arms, the pyridin-2-ylmethyl groups on the cations reported here have geometries independent of the others. Furthermore, the structure here is mixture of  $\Delta$  and  $\Lambda$  conformations of the ligand, whereas Eckenhoff's structure has chirally resolved upon crystallization.

## 3. Supramolecular features

The prominent feature of the crystal packing within this structure is the excessive positional disorder of the outer-sphere bromine anions. These are observed in a channel within the lattice (Fig. 2) that presumably has unresolvable solvent of crystallization also present. Because there are no prominent charge surfaces, packing is solely due to van der Waals interactions.

## 4. Database survey

There are six reported copper(II) bromide structures deposited in the Cambridge Structure Database incorporating the tris(pyridin-2-ylmethyl)amine ligand derivatives (Groom *et al.*, 2016; CSD Version 5.37 plus one update). Of those six structures, one is a dimer incorporating two bridging bromine ligands (Maiti *et al.*, 2007) and the remaining five are monomers. Out of the five monomer structures, three incorporate methyl or methoxy electron-withdrawing groups (Kaur *et al.*, 2015), while one incorporates hydroxyl electron-donating groups (He *et al.*, 2000). The final structure is a polymorph of that presented here: it incorporates an unsubstituted TPMA ligand framework but adopts a different space group (cubic,  $P2_13$ ) and unit-cell parameters ( $a = 12.633 \text{ \AA}$ ) due to lack of

Figure 2

disorder in the ligand framework (Eckenhoff *et al.*, 2008). Of the six total reported structures, four adopt similar distorted five-coordinate geometries as observed in complex (I), while two adopt a distorted six-coordinate geometry about the metal atom.

## 5. Synthesis and crystallization

### Synthesis of tris(pyridin-2-ylmethyl)amine (TPMA) ligand:

the TPMA ligand was synthesized according to modified literature procedures (Britovsek *et al.*, 2005). A 500 mL round-bottom flask was charged with 100 mL of dichloromethane solvent. While mixing, 2-(aminomethyl)pyridine (1.62 mL, 15.0 mmol) and sodium triacetoxyborohydride (9.63 g, 44.2 mmol) were added, generating a clear-colored solution. 2-Pyridinecarboxaldehyde (3.38 g, 31.54 mmol) was slowly added to the mixture, producing a yellow-colored solution. The reaction was allowed to mix for 24 h and interrupted with the addition of sodium hydrogen carbonate until a pH of 10 was achieved. Extractions were performed on the resulting solution with ethyl acetate and the organic layers collected. The organic layer was subsequently dried using magnesium sulfate ( $\text{MgSO}_4$ ) and solvent removed using a rotary evaporator to generate a yellow residue. This residue

was dried under vacuum for three h to produce the desired ligand as a yellow solid (4.43 g, 97%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  3.86 (s, 2H),  $\delta$  7.51 (d, 1H),  $\delta$  7.63 (t, 1H),  $\delta$  8.52 (d, 1H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  60.60, 122.35, 123.32, 136.59, 149.35, 159.81. FT-IR (solid)  $\nu$  ( $\text{cm}^{-1}$ ): 3048 (s), 3009 (s), 2920 (s), 2803 (s), 1585 (s), 1566 (s), 970 (s), 745 (s).

### Synthesis of tris(pyridin-2-ylmethyl)amine copper(II)

**bromide complex:** TPMA (0.500 g, 1.72 mmol) was dissolved in 15 mL methanol in a 100 mL round-bottom flask. Copper(II) bromide (0.384 g, 1.72 mmol) was added to the flask to give a greenish-blue-colored solution. The reaction was allowed to mix for one hour then 30 mL of diethyl ether was transferred into the flask, facilitating the precipitation of the desired complex as a green powder. The mixture was filtered and the precipitate washed with excess diethyl ether solvent. The precipitate was dried under vacuum for 30

UV-Vis:  $\lambda_{\max}$  (MeOH) = 700 nm. Green-colored single crystals suitable for X-ray analysis were obtained by slow diffusion of diethyl ether into a concentrated complex solution made in methanol.

## 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. The two ordered cations, the major occupancy component of the disordered cation and all outer-sphere bromine atoms were modeled with anisotropic atomic displacement parameters. The minor occupancy component of the disordered cation was modeled with isotropic atomic displacement parameters. Hydrogen atoms were included in geometrically calculated positions with C—H = 0.99 (methylene) and 0.95 Å (aromatic) and *U*<sub>iso</sub>(H) = 1.2*U*<sub>eq</sub>(C).

The disorder of the pyridin-2-ylmethyl groups was observed as residual electron density oriented in approximately a mirror to the major occupancy components. The occupancies of the two components were refined summed to unity, yielding an approximately 0.67:0.33 ratio. The pyridine rings for both

components were constrained to an ideal hexagon, with C—C = 1.39 Å.

All of the outer-sphere, non-coordinating bromine counterions were found to be disordered over multiple sites. Initially, occupancies were refined freely to identify possible site pairings. One bromine (Br4) was found to be nearly fully located at one site. In subsequent refinement cycles, residual density adjacent to the site was revealed and ultimately modeled as a bromine disordered over two sites with occupancies 0.80:0.20. Two bromine sites whose occupancies refined independently to nearly 50% were both set to 50% occupancy and assumed to be disorder of the same bromine atom (Br5/5A). Final residual electron density ranging from 8 to 13 e Å<sup>-3</sup> was observed. Because an additional bromine was required for charge balance and there were no other counter-ions used during synthesis, it was assumed that the final bromine was disordered over multiple sites, presumably in concert with solvent from crystallization. Ultimately, seven locations were refined as partial-occupancy bromine atoms with a total occupancy summed to unity, yielding a 0.13:0.17:0.17:0.20:0.11:0.12:0.10 ratio of sites. The solvent contribution could not be reliably modeled.

## Acknowledgements

The authors would like to thank all students who participated in this laboratory experiment for their contribution and the University of Notre Dame for instrument support.

### Special details

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** The outer sphere bromine anion atoms were all found to be disordered over multiple sites. Br4/4A was found to occupy two sites close to each other and was refined with occupancies summed to unity yielding an approximate 0.83:0.17 ratio. Br5/5A was modeled as two half occupancy bromine atoms from an initial, independent, refinement of the occupancies for these sites. Br6 is disordered over multiple sites. Occupancies of the sites were refined summed to unity yielding an approximately 0.14:0.17:0.17:0.20:0.11:0.12:0.09 ratio of site occupancies.

Attempts to model this disorder as undifferentiated solvent did not meet with success. Furthermore, because the electron density associated with this is located within the envelope developed by SQUEEZE, this routine could not be employed. The result is that there is some additional residual electron density that cannot be reliably accounted for.

Presumably there is solvent of crystallization present at the sites when they are not occupied by anions. This was not modeled.
