The structures of three related complexes of general formula $M(pds)(nab)_2$ [pds is the peroxodisulfate anion and nab is an nitrogen-containing aromatic base], *viz.* bis(2,9-dimethyl-1,10-phenanthroline- κ^2N,N')(peroxodisulfato- κ^2O,O')cadmium, $[Cd(S_2O_8)(C_{14}H_{12}N_2)_2]$, (V), bis(3,4,7,8-tetramethyl-1,10-phenanthroline- κ^2N,N')(peroxodisulfato- κ^2O,O')zinc, $[Zn(S_2O_8)(C_{16}H_{16}N_2)_2]$, (VI), and bis(3,4,7,8-tetramethyl-1,10-phenanthroline- κ^2N,N')(peroxodisulfato- κ^2O,O')-cadmium, $[Cd(S_2O_8)(C_{16}H_{16}N_2)_2]$, (VII), present the same topological coordination, with three chelating ligands in an MN_4O_2 polyhedron. The main difference resides in the fact that the first two complexes are bisected by a crystallographic twofold axis, thus providing a symmetrical environment to the cation, while in the third one this symmetry is disrupted into a clearly unsymmetrical disposition, probably by way of an unusually strong intramolecular C—H···O hydrogen bond. The situation is compared with similar interactions in the literature. The structure of (V) is based on a redetermination in the correct space group $C2/c$ of the structure originally described in the Cc space group [Harvey *et al.* (2001). *Aust. J. Chem.* **54**, 307–311; Marsh (2004). *Acta Cryst. B* **60**, 252–253].

1. Chemical context

In the last fifteen years we have made several contributions to the structural chemistry of group XII divalent cations, in particular Cd and Zn, complexed by the peroxodisulfate anion $S_2O_8^{2-}$ (pds) and several nitrogen-containing aromatic bases (nab). In all these cases, the basic general formula appeared to be $M(pds)(nab)_2$, plus the possible inclusion of some water

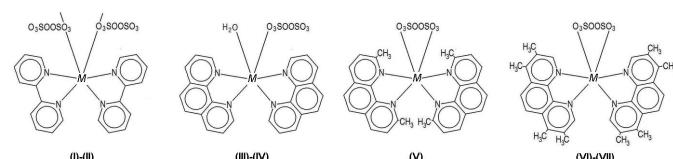

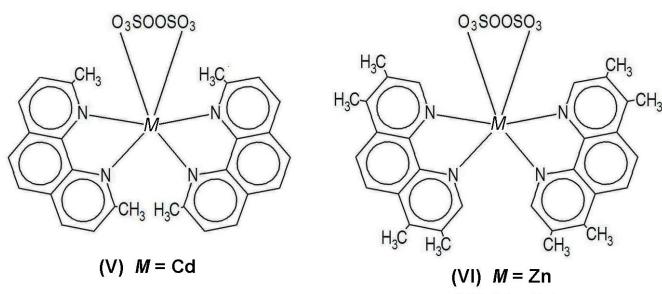

Figure 1

The different coordination modes in the $M(pds)(nab)_2$ family. (I): $\{[Cd(pds)(Bpy)_2]_n\}$, $P\bar{1}$ (Harvey *et al.*, 2001a); (II): $\{[Hg(pds)(Bpy)_2]_n\}$, $P2_1/n$ (Díaz de Vivar *et al.*, 2005); (III): $Cd(pds)(Phen)_2(H_2O)$, $P\bar{1}$ (Harvey *et al.*, 2001b); (IV): $Zn(pds)(Phen)_2(H_2O)$, $P\bar{1}$ (Harvey *et al.*, 2011); (V): $Cd(pds)(DMPhen)_2$, $C2/c$ (Harvey *et al.*, 2001b; Marsh, 2004, and this work); (VI): $Zn(pds)(TMPhen)_2$, $P\bar{1}$ (this work); (VII): $Cd(pds)(TMPhen)_2$, $Pbcn$ (this work). Ligand code: Bpy = 2,2'-bipyridine; $Phen$ = 1,10-phenanthroline, $DMPhen$ = 2,9-dimethyl-1,10-phenanthroline, $TMPhen$ = 3,4,7,8-tetramethyl-1,10-phenanthroline.

molecules, either coordinating or as a solvate (details of these complexes, including the ones to be described in the present work, are summarized in Fig. 1). Even if too few structures are reported to make any confident statistical analysis, the results suggest some kind of a trend between the identity of the nitrogen-containing base and the way the *pds* anion performs in coordination. Thus, for the smallest one, *nab* = 2,2'-bipyridine (*Bpy*), the structures obtained [(I) and (II)] show two coordinating *pds* units in a bridging –O–S–O– mode. For the intermediate *nab* = 1,10-phenanthroline (*Phen*), one of these *pds* appears to be replaced by a (smaller) coordinating water molecule, while the bound *pds* acts as a pendant mono-coordinating ligand [(III) and (IV)]. Finally, at the beginning of this work we had at hand only one single example of a relatively larger *nab* species, represented by *nab* = 2,9-dimethyl-1,10-phenanthroline, [*DMPhen*, (V)], where the single coordinating *pds* folds into itself to bind through both ends, acting in a chelating fashion. Furthermore, in both compounds of each pair of homologues (I)–(II) and (III)–(IV), the anion displays very similar conformations, defined by selected dihedral angles (Harvey *et al.*, 2011).

In order to go further in this analysis we synthesized two new complexes of this sort, with $M = \text{Zn}$ (VI) and $M = \text{Cd}$ (VII), and with a common, tetra-methylated *nab* ligand, 3,4,7,8-tetramethyl-1,10-phenanthroline (*TMPhen*). We shall see that they present the same topology as compound (V), but with subtle, interesting differences regarding intramolecular interactions which will be discussed in detail. Unlike what happens in the (I)–(II) and (III)–(IV) homologues, in (VI) and (VII) the anion displays remarkably different conformations (Harvey *et al.*, 2011). Since a comparison with the *DMPhen* structure (V) will be an important part of the discussion, and taking into account that the available data in the correct space group *C2/c* [as disclosed by Marsh (2004)] come from an averaging process (without further refinement) of previous results in *Cc* by our team (Harvey *et al.*, 2001*b*), we indulge in including herein, for completeness, a fresh refinement in *C2/c* based on the original data for this structure, in addition to the synthesis and crystal structure of the two new complexes, (VI) and (VII). Even though we shall restrict this discussion to the *pds* anion, it is pertinent to state that the tetrathionate anion ($\text{S}_4\text{O}_6^{2-}$) behaves in a rather similar way, and that the tetrathionate Zn and Cd complexes with *nab* = *DMBpy* = 4,4'-dimethyl-2,2'-bipyridine (Harvey *et al.*, 2013) have a similar coordination disposition to (V), (VI) and (VII).

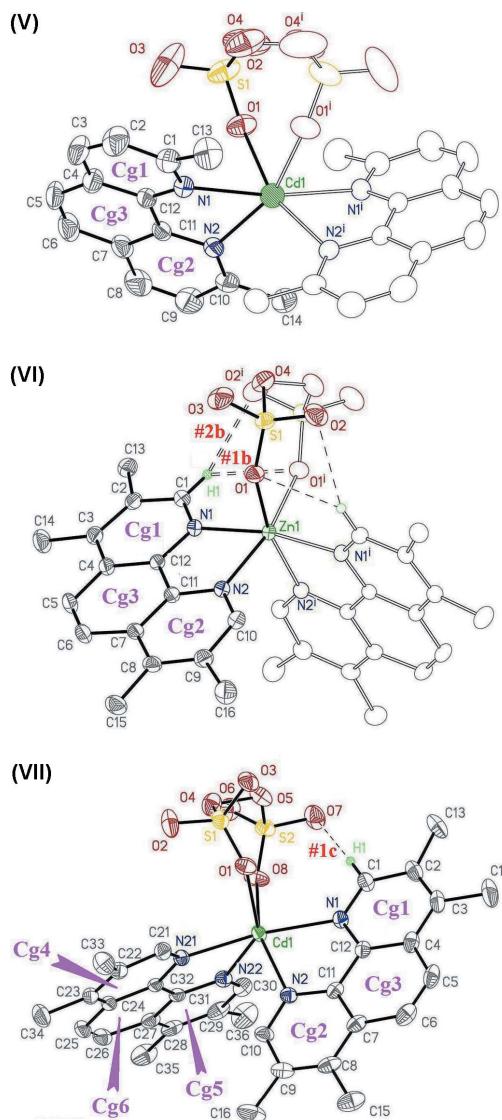

Figure 2

2. Structural commentary

The Zn complex (VI) crystallizes in space group *Pbca*, and the complete molecule is bisected by a twofold symmetry axis, hence only half of the molecule is independent ($Z' = 1/2$); even if in a different space group, these properties are shared by structure (V). The Cd counterpart (VII), in turn, crystallizes in space group *P\bar{1}* with a full molecule in the asymmetric unit.

All three compounds present a topologically similar molecular configuration (Fig. 2), consisting in a central cation to which three bidentate chelating ligands bind, *viz.* two *N,N'*-*nab* and one *O,O'*-*pds* units. In particular, the ‘close’ character of the *pds* anion is in line with the trend so far observed, that methylated bases favour the chelating behaviour of *pds*.

Coordination distances in all three compounds are basically featureless, and agree with the expected values for each cation–ligand pair. However, a difference arises in the asym-

metric way in which the ligands bind in (VII), contrasting dramatically with the twofold arrangement in (V) and (VI).

The chelating character of the ligands involved induces highly distorted coordination polyhedra. Proof of this is presented in Table 1, which shows the departure of the '*trans*' angles in (V), (VI) and (VII) from their expected values of 180° for a regular octahedron. This makes the polyhedra difficult to classify, and impairs the description of coordination in terms of any regular model. In this regard, all three compounds are suitable for the analysis *via* the Vectorial Bond Valence Model (VBVM) suggested by Harvey *et al.* (2006), an approach tending to a simpler description of multidentate binding, in which the action of each ligand is integrated into a single interaction vector, or VBV (Vectorial Bond Valence), derived from the individual bond valences of the coordinating atoms. VBVM predicts a nil resultant of the vectorial sum of all the VBV vectors and, as a consequence, in this particular case of three-ligand coordination geometry, their disposition in a planar array. The first condition is complied satisfactorily with a very short resultant for the Bond Valence Vectors [0.08, 0.03 and 0.08 valence units for (V), (VI) and (VII), respectively]. The second requirement (planar array of vectors), applies *sensu stricto* in (V) and (VI), due to the intrinsic twofold symmetry around the cation, and it falls well within experimental error in (VII), where the calculated angles between Bond Valence Vectors add up to $359.5 (3)^\circ$ and the plane defined by their extremes leave the Cd^{II} atom only 0.09 (2) \AA aside.

As an unwitting bonus of this description, these planes appear as a natural reference frame for describing ligand orientations in the polyhedra, evidencing in (V) and (VI) their adherence to twofold symmetry and in (VII) significant departures from a symmetric arrangement. This can be visualized in Fig. 3, where a schematic representation (with an exaggerated perspective) is made of the ligand bites (open bonds) as well as the VBV representing their joint effect as a ligand (solid lines). At the left, the explanation of a group of angles helping to describe the orientation of the coordination planes is provided: angles labeled α give account of the

Table 2Distortion angles as defined in Fig. 3 ($^\circ$).

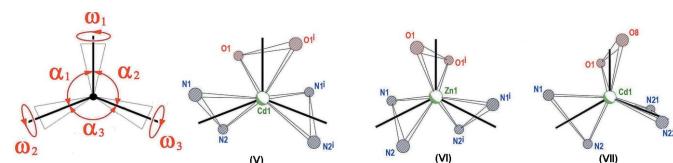

Angle	(V)	(VI)	(VII)
α_1	111.1	116.7	119.0
α_2	111.1	116.7	111.0
α_3	137.9	126.6	129.4
ω_1	49.0	67.5	71.1
ω_2	55.9	55.8	27.0
ω_3	55.9	55.8	84.7

angular separation in the plane between vectors, while those labeled ω measure the out-of-plane rotation of the coordination planes around the corresponding VBV vectors. It is apparent, either by visual inspection of Fig. 3 or through the analysis of the ω values (Table 2), that the coordination polyhedron in (VII) is abnormally distorted. Since this could be the result of packing strain (intermolecular interactions) or just due to genuine intramolecular forces, we shall analyze and compare the three packing arrangements for (V), (VI) and (VII).

3. Supramolecular features

The most relevant, non-covalent interactions involved are presented in Table 3 (hydrogen bonds) and Table 4 (π – π contacts). The second column includes a code, which labels each interaction for easy reference; in the last column, the role the interaction plays in packing is listed.

Fig. 4 presents packing views of all three structures: it is apparent that in spite of crystallizing in different space groups, with different symmetry environments, the *leitmotifs* are strictly the same, *viz.* π – π bound chains running along [101] in (V) and [001] in (VI) and (VII), the link being the stacking interaction appearing in Table 4, which in all cases connect inversion-related moieties. Except for the rather strong #2c in (VII), the remaining intermolecular interactions are weak and serve either to strengthen the link within the chains (marked as 'intrachain' in the tables) or to weakly connect parallel chains with each other ('interchain') to end up defining weakly bound three-dimensional structures. This description is valid for all three structures, and there is nothing special about the packing interactions in (VII) so as to ascribe to them the responsibility for the coordination 'anomaly'. In fact, interaction #2c, which due to its outstanding character might be thought of as a candidate to blame, involves the 'well behaved'

**Figure 3**

Schematic representation of the ligand distortion. In open bonds, the chelating ligands, (drawn as connected to each other, for clarity); in solid lines, the VBV vectors, representing the integrated action of each ligand. Angle codes are explained in the text.

N21,N22-TMPHen and not the one departing from geometrical regularity (*N1,N2-TMPHen*). This fact can be clearly appreciated in Fig. 4 (bottom).

As far as intramolecular interactions are concerned, the symmetric cases (V) and (VI) present different behaviours regarding these contacts. Methyl groups at the 2,9 positions inhibit structure (V) from entering into any significant $(\text{C}-\text{H})_{\text{arom}}\cdots \text{O}_{\text{pds}}$ intramolecular contact, as suggested in Fig. 2 and disclosed in Table 3, where only weak, intermolecular interactions are to be found. Structure (VI), in turn, having sites 2 and 9 free, is amenable of a closer approach of $(\text{C}-\text{H})_{\text{arom}}$ donors and O_{pds} acceptors, and in fact a pair of weak bonds set up (#1b and #2b, Fig. 2 and Table 3). However, it is in structure (VII) where things depart from normal, with a second unusually short and almost straight $\text{C}-\text{H}\cdots \text{O}$ bond internally linking the ‘offending’ *N1,N2-TMPHen* ligand and

the *pds* anion in the same coordination sphere (interaction #1c in Table 3). In order to evaluate, at least in comparative terms the real significance of this bond (and, by extension, the similar #2c), we made some CSD (Version 5.37; Groom *et al.*, 2016) data mining and statistical comparisons.

When comparing interaction #1c with its peers in the database, we looked for $(\text{C}-\text{H})_{\text{arom}}\cdots \text{O}$ intramolecular bonds with almost no restrictions (*viz.* $2 \text{\AA} < \text{H}\cdots \text{O} < 3.0 \text{\AA}$; $120^\circ < \text{C}-\text{H}\cdots \text{O} < 180^\circ$). The results (from *ca* 30000 entries analysed) are quoted in Fig. 5, where the distance (*a*) and angle (*b*) histograms, as well as the combined scatterplot (*c*) are presented. The two hydrogen bonds in (VI), marked in cyan, appear to be absolutely average, as are their structural consequences. The one in (VII) (marked in red), instead appears endowed with a rather unique character, in particular its nearly straight $\text{C}-\text{H}\cdots \text{O}$ configuration. We tried to eval-

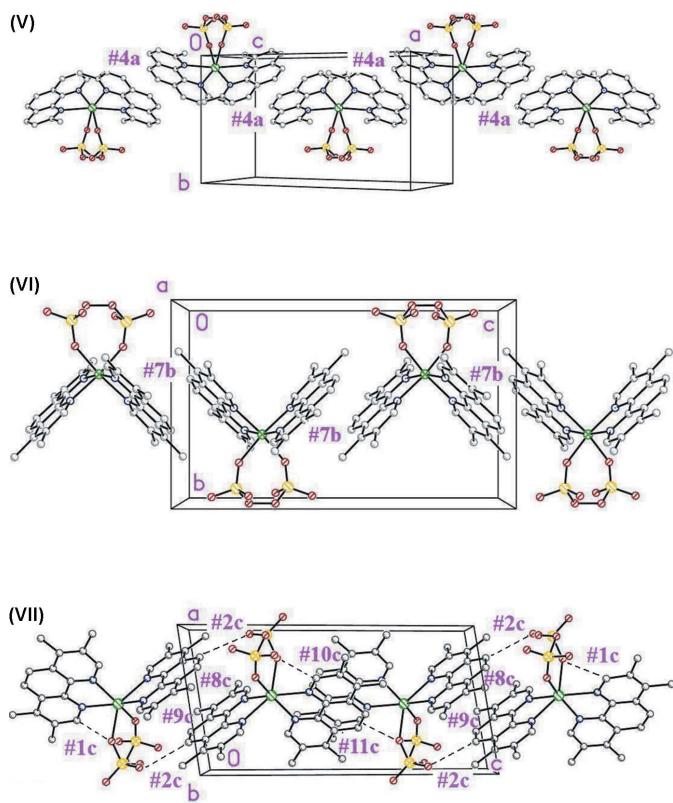

Figure 4
The π -bonded one-dimensional leitmotifs in all three structures. Stacking interactions labeled as in Table 4. H atoms have been omitted for clarity.

uate how frequent this kind of disrupting behaviour was (in terms of molecular distortions) among comparable C–H \cdots O interactions. Inspection of the occurrences found showed that they tended to appear either in monocoordinating ligands or pendant groups, in all cases with free rotations at some point in the chain, which made the C–H \cdots O contact almost irrelevant in terms of configurational energy. What makes the case in (VII) unusual is the chelating character of the ligands involved, with the concomitant deformation of the coordination polyhedron.

Summarizing, there are in principle two possible reasons for the molecular geometry in (VII): either the (packing-assisted) asymmetry with which ligand (*N*1,*N*2)*TMPPhen* binds Cd1 is the reason allowing for an unusual closeness between C1–H1 and O7, giving room to a strong hydrogen bond, or (the other way round) it is this hydrogen bond that is the cause, and the asymmetric coordination its concomitant consequence. The lack of significant intermolecular packing interactions which may justify the distortion in (VII), in addition to the outstanding character of the #1c C–H \cdots O bond seem to sustain the latter hypothesis, *viz.* that it is the presence of this hydrogen bond ('weak' among 'strong' but 'strong' among 'weak') which disrupts the expected symmetrical geometry in the Cd(*pds*)*(TMPPhen)*₂ unit, constituting thus a rare case of a non-conventional C–H \cdots O bond being responsible for a surprising molecular configuration.

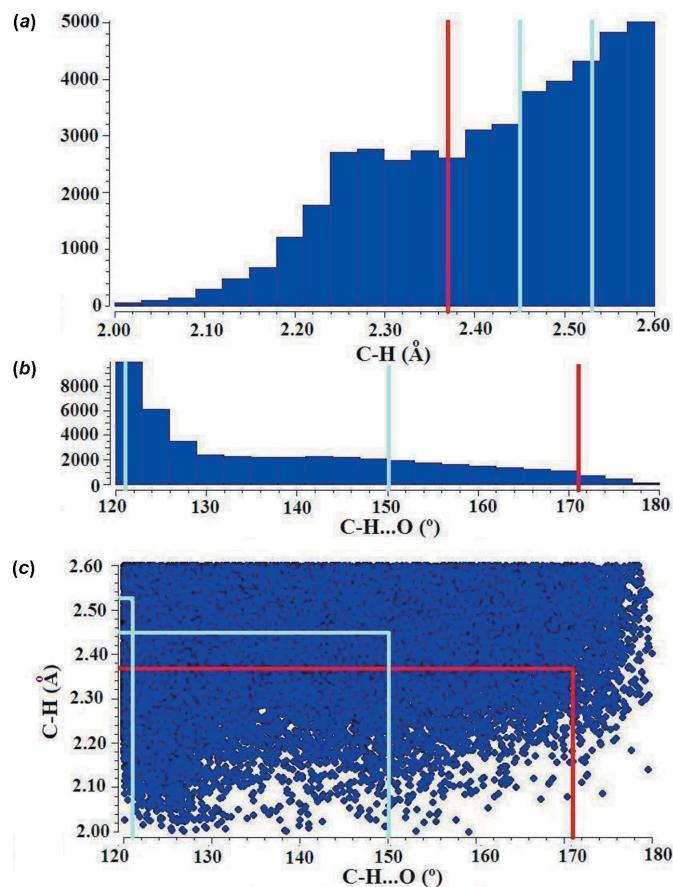

Figure 5
Statistical analysis of intramolecular (C–H)_{arom} \cdots O bonds as found in the literature. In cyan, those found in (VI); in red, the one in (VII).

4. Synthesis and crystallization

Compounds (VI) and (VII) were synthesized in a similar fashion: a solution (4 ml) containing 0.050 mmol (13.5 mg) of potassium peroxodisulfate and 0.100 mmol (23.6 mg) of 3,4,7,8-tetramethyl-1,10-phenanthroline (in a 3:1 *v/v* methanol:water mixture) were added to 0.050 mmol of the corresponding metal acetate [Zn(OAc)₂: 11.0 mg; Cd(OAc)₂: 13.3 mg]. An initial precipitate of extremely small needles was readily digested, but in a few days a crop of single crystals suitable for X-ray diffraction were obtained, in the form of colorless blocks. For the synthesis of (V), see Harvey *et al.* (2001b).

5. Refinement details

Data collection details and refinement results for (V), (VI) and (VII) are summarized in Table 5. The data set for (V) is the same used in the original publication (Harvey *et al.*, 2001b) reporting the structure refined in the *Cc* space group. All hydrogen atoms were found in a difference Fourier map, but further idealized and allowed to ride on their parent atoms with C–H = 0.93–0.98 Å, and $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ or $1.5U_{\text{eq}}(\text{C})$ for methyl H atoms. A rotating model was used for

Three phenanthroline–metal complexes with topologically similar but geometrically different conformations

Miguel Angel Harvey, Sebastián Suarez and Ricardo Baggio

Computing details

Data collection: *P3/P4-PC* (Siemens, 1991) for (V); *CrysAlis PRO* (Oxford Diffraction, 2009) for (VI), (VII). Cell refinement: *P3/P4-PC* (Siemens, 1991) for (V); *CrysAlis PRO* (Oxford Diffraction, 2009) for (VI), (VII). Data reduction: *P3/P4-PC* (Siemens, 1991) for (V); *CrysAlis PRO* (Oxford Diffraction, 2009) for (VI), (VII). For all compounds, program(s) used to solve structure: *SHELXS97* (Sheldrick, 2008); program(s) used to refine structure: *SHELXL2014* (Sheldrick, 2015); molecular graphics: *SHELXTL* (Sheldrick, 2008); software used to prepare material for publication: *SHELXL2014* (Sheldrick, 2015) and *PLATON* (Spek, 2009).

(V) Bis(2,9-dimethyl-1,10-phenanthroline- $\kappa^2\text{N},\text{N}'$)(peroxodisulfato- $\kappa^2\text{O},\text{O}'$)cadmium(II)

Crystal data

Data collection

Siemens R3m
 diffractometer
 Radiation source: fine-focus sealed tube
 Graphite monochromator
 $\omega/2\theta$ scans
 Absorption correction: ψ scan
 (*P3/P4-PC*; Siemens, 1991)
 $T_{\min} = 0.70$, $T_{\max} = 0.88$
 2562 measured reflections

2495 independent reflections
 2300 reflections with $I > 2\sigma(I)$
 $R_{\text{int}} = 0.040$
 $\theta_{\max} = 25.0^\circ$, $\theta_{\min} = 2.2^\circ$
 $h = 0 \rightarrow 26$
 $k = 0 \rightarrow 11$
 $l = -19 \rightarrow 15$
 2 standard reflections every 98 reflections
 intensity decay: 2%

Refinement

Refinement on F^2
 Least-squares matrix: full
 $R[F^2 > 2\sigma(F^2)] = 0.027$
 $wR(F^2) = 0.073$
 $S = 1.11$
 2495 reflections

197 parameters
 195 restraints
 Hydrogen site location: inferred from
 neighbouring sites
 H-atom parameters constrained

$$w = 1/[\sigma^2(F_o^2) + (0.0424P)^2 + 2.2422P]$$

where $P = (F_o^2 + 2F_c^2)/3$
 $(\Delta/\sigma)_{\max} < 0.001$

$$\Delta\rho_{\max} = 0.47 \text{ e } \text{\AA}^{-3}$$

$$\Delta\rho_{\min} = -0.41 \text{ e } \text{\AA}^{-3}$$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Symmetry code: (i) $-x, y, -z+1/2$.

(VI) Bis(3,4,7,8-tetramethyl-1,10-phenanthroline- $\kappa^2 N,N'$)(peroxodisulfato- $\kappa^2 O,O'$)zinc(II)

Crystal data

$[Zn(S_2O_8)(C_{16}H_{16}N_2)_2]$
 $M_r = 730.10$
Orthorhombic, $Pbcn$
 $a = 15.6244$ (2) Å
 $b = 10.8803$ (2) Å
 $c = 17.9446$ (3) Å
 $V = 3050.55$ (9) Å³
 $Z = 4$
 $F(000) = 1512$

$D_x = 1.590$ Mg m^{−3}
Mo $K\alpha$ radiation, $\lambda = 0.71073$ Å
Cell parameters from 3997 reflections
 $\theta = 4.0\text{--}28.1^\circ$
 $\mu = 1.00$ mm^{−1}
 $T = 294$ K
Blocks, colorless
0.35 × 0.20 × 0.16 mm

Data collection

Oxford Diffraction Gemini CCD S Ultra
diffractometer
 ω scans, thick slices
Absorption correction: multi-scan
(CrysAlis PRO; Oxford Diffraction, 2009)
 $T_{\min} = 0.76$, $T_{\max} = 0.84$
63344 measured reflections

3988 independent reflections
3341 reflections with $I > 2\sigma(I)$
 $R_{\text{int}} = 0.049$
 $\theta_{\max} = 29.3^\circ$, $\theta_{\min} = 3.8^\circ$
 $h = -21 \rightarrow 21$
 $k = -14 \rightarrow 14$
 $l = -23 \rightarrow 23$

Refinement

Refinement on F^2
Least-squares matrix: full
 $R[F^2 > 2\sigma(F^2)] = 0.033$
 $wR(F^2) = 0.092$
 $S = 1.04$
3988 reflections
217 parameters
0 restraints

Hydrogen site location: inferred from
neighbouring sites
H-atom parameters constrained
 $w = 1/[c^2(F_o^2) + (0.0436P)^2 + 2.8456P]$
where $P = (F_o^2 + 2F_c^2)/3$
 $(\Delta/\sigma)_{\max} < 0.001$
 $\Delta\rho_{\max} = 0.47$ e Å^{−3}
 $\Delta\rho_{\min} = -0.53$ e Å^{−3}

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

(VII) Bis(3,4,7,8-tetramethyl-1,10-phenanthroline- κ^2N,N')(peroxodisulfato- κ^2O,O')cadmium(II)

Crystal data

$M_r = 777.13$

Triclinic, $P\bar{1}$

$a = 8.601 (3) \text{ \AA}$

$b = 11.063 (4) \text{ \AA}$

$c = 16.932 (5) \text{ \AA}$

$\alpha = 98.788 (5)^\circ$

$\beta = 97.713 (5)^\circ$

$\gamma = 97.943 (5)^\circ$

$V = 1557.0 (9) \text{ \AA}^3$

$Z = 2$

$F(000) = 792$

$D_x = 1.658 \text{ Mg m}^{-3}$

Mo $K\alpha$ radiation, $\lambda = 0.71069 \text{ \AA}$

Cell parameters from 6894 reflections

$\theta = 3.8\text{--}27.7^\circ$

$\mu = 0.90 \text{ mm}^{-1}$

$T = 294 \text{ K}$

Blocks, colorless

$0.28 \times 0.16 \times 0.14 \text{ mm}$

Data collection

Oxford Diffraction Gemini CCD S Ultra diffractometer
 ω scans, thick slices
Absorption correction: multi-scan (CrysAlis PRO; Oxford Diffraction, 2009)
 $T_{\min} = 0.76$, $T_{\max} = 0.84$
41025 measured reflections

7888 independent reflections
6692 reflections with $I > 2\sigma(I)$
 $R_{\text{int}} = 0.057$
 $\theta_{\max} = 29.6^\circ$, $\theta_{\min} = 3.7^\circ$
 $h = -11 \rightarrow 11$
 $k = -15 \rightarrow 14$
 $l = -22 \rightarrow 23$

Refinement

Refinement on F^2
Least-squares matrix: full
 $R[F^2 > 2\sigma(F^2)] = 0.033$
 $wR(F^2) = 0.071$
 $S = 1.07$
7888 reflections
432 parameters
0 restraints

Hydrogen site location: inferred from neighbouring sites
H-atom parameters constrained
 $w = 1/[\sigma^2(F_o^2) + (0.0258P)^2 + 0.357P]$
where $P = (F_o^2 + 2F_c^2)/3$
 $(\Delta/\sigma)_{\max} = 0.001$
 $\Delta\rho_{\max} = 0.54 \text{ e } \text{\AA}^{-3}$
 $\Delta\rho_{\min} = -0.57 \text{ e } \text{\AA}^{-3}$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
