The title compound, $\left[\mathrm{Cd}_{2}\left(\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{NS}_{2}\right)_{4}\right]$, is a centrosymmetric dimer with both chelating and $\mu_{2}$-tridentate dithiocarbamate ligands. The resulting $\mathrm{S}_{5}$ donor set defines a $\mathrm{Cd}^{\mathrm{II}}$ coordination geometry intermediate between square-pyramidal and trigonal-bipyramidal, but tending towards the former. The packing features $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ and $\mathrm{C}-\mathrm{H} \cdots \pi$ interactions, which generate a three-dimensional network. The influence of these interactions, along with intra-dimer $\pi-\pi$ interactions between chelate rings, has been investigated by an analysis of the Hirshfeld surface.

## 1. Chemical context

The structural chemistry of the binary zinc-triad (group 12) dithiocarbamates $\left({ }^{-} \mathrm{S}_{2} \mathrm{CN} R R^{\prime}\right)_{2}\left(R / R^{\prime}=\right.$ alkyl/aryl), along with related 1,1-dithiolate ligands, i.e. dithiophosphates $\left[{ }^{-} \mathrm{S}_{2} \mathrm{P}(\mathrm{OR})_{2}\right]$ and dithiocarbonates (xanthates; ${ }^{-} \mathrm{S}_{2} \mathrm{COR}$ ), have long attracted the attention of structural chemists owing to their diversity of structures/supramolecular association patterns in the solid state (Cox \& Tiekink, 1997; Tiekink, 2003). The common structural motif adopted by all elements is one that features two chelating ligands and two tridentate ligands (chelating one metal atom and simultaneously bridging to a second), leading, usually, to a centrosymmetric binuclear molecule. Indeed, most zinc dithiocarbamate structures adopt this motif, but when the $R / R^{\prime}$ are bulky, a mononuclear species with tetrahedrally coordinated zinc atoms is found; significantly greater structural variety has been noted for the binary zinc dithiophosphates and xanthates (Lai et al., 2002; Tan et al., 2015). More diversity in structural motifs is noted in the binary cadmium dithiocarbamates with the recent observation of linear polymeric forms with hexacoordinated cadmium atoms (Tan et al., 2013, 2016; Ferreira et al., 2016). Systematic studies indicated solvent-mediated transformations between polymeric and binuclear structural motifs, with the latter being the thermodynamically more stable (Tan et al., 2013, 2016). The greatest structural diversity among the zinc-triad dithiocarbamates is found for the binary mercury compounds, where mononuclear, binuclear and polymeric structures have been observed, as summarized very recently (Jotani et al., 2016). Complementing the structural motifs already mentioned for zinc and cadmium is a trinuclear species, $\left\{\mathrm{Hg}\left[\mathrm{S}_{2} \mathrm{CN}(\right.\right.$ tetra-

hydroquinoline) $\left.]_{2}\right\}_{3}$ (Rajput et al., 2014), with the central $\mathrm{Hg}^{\text {II }}$ atom being hexacoordinated, as in the polymeric form, and the peripheral $\mathrm{Hg}^{\text {II }}$ atoms being coordinated as in the binuclear form, indicating the possibility that this is an intermediate metastable form in the crystallization of this compound. In light of the above, when crystals of the title compound became available, namely $\left\{\mathrm{Cd}\left[\mathrm{S}_{2} \mathrm{CN}(\mathrm{Me}) \mathrm{Ph}\right]_{2}\right\}_{2}$, (I), its crystal and molecular structures were studied, along with an evaluation of the supramolecular association in the crystal through an analysis of the Hirshfeld surface.

## 2. Structural commentary

The centrosymmetric binuclear molecule of (I) (Fig. 1) conforms to the common binuclear motif adopted by binary zinc-triad dithiocarbamates. The S1 dithiocarbamate anion forms a nearly symmetric bridge, as seen in the value of

Figure 1
The molecular structure of (I), showing the atom-labelling scheme and displacement ellipsoids at the $70 \%$ probability level. The molecule is located about a centre of inversion and unlabelled atoms are generated by the symmetry operation $(-x, 1-y, 1-z)$.

Table 2

Symmetry codes: (ii) $x+1,-y+\frac{1}{2}, z-\frac{1}{2}$; (iii) $-x, y+\frac{1}{2},-z+\frac{1}{2}$.
$\Delta(\mathrm{Cd}-\mathrm{S})=0.09 \AA=\mathrm{Cd}-\mathrm{S}_{\text {long }}-\mathrm{Cd}-\mathrm{S}_{\text {short }}$. Within the resultant $\{\mathrm{CdSCS}\}_{2}$ eight-membered ring, which adopts a chair conformation, the bridging S2 atom also forms a longer [S2$\mathrm{Cd}^{\mathrm{i}}=2.9331(8) \AA$; symmetry code: (i) $\left.-x, 1-y, 1-z\right]$ transannular interaction. The S3 dithiocarbamate ligand is strictly chelating, with $\Delta(\mathrm{Cd}-\mathrm{S})=0.08 \AA$. Reflecting the symmetric modes of coordination of the dithiocarbamate ligands, the $\mathrm{C}-\mathrm{S}$ bond lengths are equal within $5 \sigma$ (Table 1).

The resultant $\mathrm{S}_{5}$ donor set defines a highly distorted pentacoordinate geometry, with the major distortions due to the disparate $\mathrm{Cd}-\mathrm{S}$ bond lengths and the acute angles subtended at the $\mathrm{Cd}^{\mathrm{II}}$ atom by the chelating ligands (Table 1 ). The widest angle at the $\mathrm{Cd}^{\mathrm{II}}$ atom involves the S atoms forming the weaker $\mathrm{Cd}-\mathrm{S}$ interactions, i.e. $\mathrm{S} 2-\mathrm{Cd}-\mathrm{S} 4=$ 161.85 (3) ${ }^{\circ}$. A measure of the distortion of a coordination

geometry from the ideal square-pyramidal and trigonalbipyramidal geometries is given by the value of $\tau$ (Addison et al., 1984), which computes to 0.0 and 1.0 for the ideal geometries, respectively. In (I), the value of $\tau$ is 0.39 , i.e. intermediate between the two extremes, but tending towards the former.

## 3. Supramolecular features

Two specific intermolecular interactions have been identified in the molecular packing of (I), and each involves the participation of phenyl ring C3-C8 (Table 2). Phenyl-C-H $\cdots \pi$ interactions with the C3-C8 ring as the acceptor lead to supramolecular layers parallel to ( $\overline{1} 02$ ), as each binuclear molecule participates in four such interactions. The layers are connected into a three-dimensional architecture by phenyl-$\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ interactions, i.e. with the $\mathrm{C} 3-\mathrm{C} 8$ ring as donor (Fig. 2).

## 4. Hirshfeld surface analysis

The Hirshfeld surface analysis for (I) was performed as described in a recent report of a related binuclear cadmium dithiocarbamate compound (Jotani et al., 2016). On the Hirshfeld surface mapped over $d_{\text {norm }}$ in the range -0.055 to 1.371 au (Fig. 3), the bright-red spots near the C5, H5 and S1 atoms indicate respective donors and acceptors of intermolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ interactions; the other pair of faint-red spots near atoms C4 and S1 represent a weaker interaction

Figure 3
A view of the Hirshfeld surface for (I) mapped over $d_{\text {norm }}$ in the range -0.055 to 1.371 au.

Figure 4
A view of Hirshfeld surface for (I) mapped over the electrostatic potential in the range $\pm 0.048$ au.
(Table 3). The donors and acceptors of the specified $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ and $\mathrm{C}-\mathrm{H} \cdots \pi$ interactions in Table 2, and short interatomic $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ contacts (Table 3) give rise to positive and negative potentials, respectively, and are viewed as the blue

Figure 5
Views of the Hirshfeld surface mapped over (a) $d_{\text {norm }}$ about a reference molecule, highlighting the intermolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ interactions and short interatomic $\mathrm{C} \cdots \mathrm{C}$ contacts as black and red dashed lines, respectively, and (b) with shape-index property about a reference molecule. The $\mathrm{C}-\mathrm{H} \cdots \pi$ and $\pi \cdots \mathrm{H}-\mathrm{C}$ interactions are indicated with red and white dotted lines, respectively.

Table 4
Percentage contributions of the different intermolecular contacts to the Hirshfeld surface in (I).

| Contact | \% Contribution in (I) |
| :--- | :--- |
| $\mathrm{H} \cdots \mathrm{H}$ | 40.0 |
| $\mathrm{~S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}$ | 26.7 |
| $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ | 24.8 |
| $\mathrm{~S} \cdots \mathrm{~S}$ | 5.8 |
| $\mathrm{Cd} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{Cd}$ | 1.2 |
| $\mathrm{~N} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{N}$ | 0.8 |
| $\mathrm{Cd} \cdots \mathrm{S} / \mathrm{S} \cdots \mathrm{Cd}$ | 0.7 |

and red regions on Hirshfeld surface mapped over electrostatic potential (in the range $\pm 0.048 \mathrm{au}$ ) (Fig. 4). The immediate environments about a reference molecule within $d_{\text {norm }}$ and shape-index mapped Hirshfeld surface are illustrated in Figs. 5(a) and 5(b), respectively, and again highlight the influence of $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ interactions, short $\mathrm{C} 10 \cdots \mathrm{C} 15$ contacts and $\mathrm{C}-\mathrm{H} \cdots \pi$ interactions involving phenyl rings (atoms C3-C8) as the acceptor. Thus, the $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}$ interactions involving the phenyl-ring $\mathrm{C} 4, \mathrm{C} 5$ and H 5 atoms with S 1 are shown with black dashed lines in Fig. 5(a); the red dashed lines indicate short interatomic C...C contacts (Table 3). The

Figure 6
Fingerprint plots for (I): (a) overall and those delineated into (b) H $\cdots \mathrm{H}$, (c) $\mathrm{S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}$, (d) $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ and (e) $\mathrm{S} \cdots \mathrm{S}$ contacts.
$\mathrm{C}-\mathrm{H} \cdots \pi$ and their reciprocal contacts, i.e. $\pi \cdots \mathrm{H}-\mathrm{C}$, with phenyl-ring atom C 14 as donor and phenyl ring $\mathrm{C} 3-\mathrm{C} 8$ as acceptor, are shown with red and white dotted lines, respectively, on the Hirshfeld surface mapped with shape-index property in Fig. 5(b).

The overall two-dimensional fingerprint plot and those delineated into $\mathrm{H} \cdots \mathrm{H}, \mathrm{S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}, \mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ and $\mathrm{S} \cdots \mathrm{S}$ contacts (McKinnon et al., 2007) are illustrated in Figs. 6(a)$(e)$; their relative contributions to the Hirshfeld surface are summarized quantitatively in Table 4. The relatively low contribution of $\mathrm{H} \cdots \mathrm{H}$ contacts to the Hirshfeld surface results from the involvement of surface H atoms in intermolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{S}, \mathrm{C}-\mathrm{H} \cdots \pi$ and $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ contacts. It is apparent from the fingerprint plot delineated into $\mathrm{H} \cdots \mathrm{H}$ contacts (Fig. 6b) that $\mathrm{H} \cdots \mathrm{H}$ contacts do not exert much influence on the molecular packing, as their interatomic distances are greater than the sum of their van der Waals radii, i.e. $d_{\mathrm{e}}+d_{\mathrm{i}}>$ $2.8 \AA$. A pair of peaks appearing in the fingerprint plot delineated into $\mathrm{S} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{S}$ contacts at $d_{\mathrm{e}}+d_{\mathrm{i}} \sim 2.8 \AA$ (Fig. $6 c$ ) arise from the $\mathrm{C} 5-\mathrm{H} 5 \cdots \mathrm{~S} 1$ interaction; the weaker $\mathrm{C} 4 \cdots \mathrm{H} 4 \cdots \mathrm{~S} 1$ interaction and short interatomic $\mathrm{H} \cdots \mathrm{S} / \mathrm{S} \cdots \mathrm{H}$ contacts involving the S 3 atom (Table 3) are viewed as a pair of thin green lines aligned at $d_{\mathrm{e}}+d_{\mathrm{i}} \sim 2.9 \AA$.

The distribution of points showing the superimposition of a forceps-like shape on characteristic wings in the fingerprint plot delineated into $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ contacts (Fig. 6d) indicate the significance of these contacts through the presence of $\mathrm{C}-$ $\mathrm{H} \cdots \pi$ interactions and short interatomic $\mathrm{C} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{C}$ contacts in the crystal. A pair of green lines within the forceps also indicates the influence of these contacts. Finally, an arrowshaped distribution of green points in the centre in the plot corresponding to $\mathrm{S} \cdots \mathrm{S}$ contacts (Fig. 6e), together with the contribution from Cd‥S/S $\cdots \mathrm{Cd}$ contacts to the Hirshfeld surface (Table 4), show the presence of intramolecular $\pi-\pi$ stacking interactions between the $\mathrm{Cd} / \mathrm{S} 1 / \mathrm{C} 1 / \mathrm{S} 2$ chelate rings of inversion-related molecules $[C g \cdots C g=3.6117$ (11) $\AA$; symmetry code: $-x, 1-y, 1-z]$. The small contributions from $\mathrm{Cd} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{Cd}$ and $\mathrm{N} \cdots \mathrm{H} / \mathrm{H} \cdots \mathrm{N}$ contacts (Table 4) do not impact significantly on the molecular packing.

## 5. Database survey

The dithiocarbamate ligand featured in (I) has been reported in several other crystal structures (Groom et al., 2016). Indeed, the binary zinc (Baba et al., 2002) and mercury (Onwudiwe \& Ajibade, 2011a,b) structures have been reported already, so, in this sense, the structure of (I) completes the series. The zinc compound adopts the common binuclear motif (Baba et al., 2002). More interesting is the fact that for the mercury structure, both mononuclear (Onwudiwe \& Ajibade, 2011a) and binuclear (Onwudiwe \& Ajibade, 2011b) forms have been reported (Tan et al., 2015). As to the other main group element structures, the binary dithiocarbamate compounds of antimony(III) (Baba et al., 2003) and bismuth(III) (Yin et al., 2004), including an acetonitrile solvate (Lai \& Tiekink, 2007), have been described. These, too, present the same structural features as reported for the overwhelming majority of related
antimony(III) (Liu \& Tiekink, 2005) and bismuth(III) dithiocarbamate compounds (Lai \& Tiekink, 2007).

## 6. Synthesis and crystallization

All chemicals and solvents were used as purchased without purification, and all reactions were carried out under ambient conditions. The melting point was determined using an Electrothermal digital melting-point apparatus and was uncorrected. The IR spectrum was obtained on a PerkinElmer Spectrum 400 FT Mid-IR/Far-IR spectrophotometer from 4000 to $400 \mathrm{~cm}^{-1} .{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded at room temperature in DMSO- $d_{6}$ solution on a Jeol ECA 400 MHz FT-NMR spectrometer.

Sodium methylphenyldithiocarbamate ( $1.0 \mathrm{mmol}, 0.205 \mathrm{~g}$ ) in methanol ( 25 ml ) was added to cadmium chloride $(1.0 \mathrm{mmol}, 0.183 \mathrm{~g})$ in methanol $(10 \mathrm{ml})$. The resulting mixture was stirred and refluxed for 2 h . The filtrate was evaporated until an off-white precipitate was obtained, which was recrystallized in methanol. Slow evaporation of the filtrate yielded colourless crystals of the title compound (yield: $0.194 \mathrm{~g}, 61 \%$; m.p. 473 K ). IR ( $\mathrm{cm}^{-1}$ ): 1491 (m) [ $\nu(\mathrm{C}-\mathrm{N})$ ], $1160(m), 964(s)[v(\mathrm{C}-\mathrm{S})] \mathrm{cm}^{-1} .{ }^{1} \mathrm{H}$ NMR: $\delta 7.26-7.42(m$, 5 H , aromatic H), $2.05\left(s, 3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR: $\delta 46.6$ (Me) 125.6, 128.4, 129.6, 147.9 (aromatic C), $207.8\left(\mathrm{CS}_{2}\right)$.

## 7. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 5. Carbon-bound H atoms were placed in calculated positions $(\mathrm{C}-\mathrm{H}=0.95-0.98 \AA)$ and were included in the refinement in the riding-model approximation, with $U_{\text {iso }}(\mathrm{H})$ values set at $1.2-1.5 U_{\text {eq }}(\mathrm{C})$.

## supporting information

Acta Cryst. (2017). E73, 429-433 [https://doi.org/10.1107/S2056989017002705]
$\operatorname{Bis}\left(\mu_{2}-N\right.$-methyl- $N$-phenyldithiocarbamato) $-\kappa^{3} S, S^{\prime}: S ; \kappa^{3} S: S, S^{\prime}$-bis [( $N$-methyl- $N$ -phenyldithiocarbamato- $\kappa^{2} S, S^{\prime}$ )cadmium]: crystal structure and Hirshfeld surface analysis

Siti Aisyah Nabilah Suwardi, See Mun Lee, Kong Mun Lo, Mukesh M. Jotani and Edward R. T. Tiekink

## Computing details

Data collection: CrysAlis PRO (Agilent, 2013); cell refinement: CrysAlis PRO (Agilent, 2013); data reduction: CrysAlis PRO (Agilent, 2013); program(s) used to solve structure: SHELXS97 (Sheldrick, 2008); program(s) used to refine structure: SHELXL2014 (Sheldrick, 2015); molecular graphics: ORTEP-3 for Windows (Farrugia, 2012) and DIAMOND (Brandenburg, 2006); software used to prepare material for publication: publCIF (Westrip, 2010).
$\operatorname{Bis}\left(\mu_{2}-N\right.$-methyl- $N$-phenyldithiocarbamato)- $\kappa^{3} S, S^{\prime}: S ; \kappa^{3} S: S, S^{\prime}$-bis[( $N$-methyl- $N$-phenyldithiocarbamato$\kappa^{2} S, S^{\prime}$ )cadmium (II)]

## Crystal data

$\left[\mathrm{Cd}_{2}\left(\mathrm{C}_{8} \mathrm{H}_{8} \mathrm{NS}_{2}\right)_{4}\right]$
$M_{r}=953.92$
Monoclinic, $P 2{ }_{1} / c$
$a=12.7972$ ( 6 ) $\AA$
$b=6.4445$ (3) $\AA$
$c=22.582$ (1) $\AA$
$\beta=98.247(4)^{\circ}$
$V=1843.11$ (15) $\AA^{3}$
$Z=2$

## Data collection

Agilent SuperNova Dual Source diffractometer with an Atlas detector Radiation source: SuperNova (Mo) X-ray Source
Mirror monochromator
Detector resolution: 10.4041 pixels $\mathrm{mm}^{-1}$
$\omega$ scan
Absorption correction: multi-scan
(CrysAlis PRO; Agilent, 2013)
$F(000)=952$
$D_{\mathrm{x}}=1.719 \mathrm{Mg} \mathrm{m}^{-3}$
Mo $K \alpha$ radiation, $\lambda=0.71073 \AA$
Cell parameters from 4387 reflections
$\theta=3.4-29.8^{\circ}$
$\mu=1.64 \mathrm{~mm}^{-1}$
$T=100 \mathrm{~K}$
Block, colourless
$0.20 \times 0.15 \times 0.10 \mathrm{~mm}$
$T_{\min }=0.731, T_{\text {max }}=1.000$
11881 measured reflections
4894 independent reflections
3804 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.037$
$\theta_{\text {max }}=30.2^{\circ}, \theta_{\text {min }}=3.2^{\circ}$
$h=-12 \rightarrow 17$
$k=-9 \rightarrow 8$
$l=-29 \rightarrow 30$

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.037$
$w R\left(F^{2}\right)=0.086$
$S=1.05$
4894 reflections
210 parameters
0 restraints

Primary atom site location: structure-invariant direct methods
Hydrogen site location: inferred from neighbouring sites
H -atom parameters constrained
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}^{2}\right)+(0.0331 P)^{2}+0.5876 P\right]$ where $P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$
$(\Delta / \sigma)_{\max }=0.001$
$\Delta \rho_{\text {max }}=0.72 \mathrm{e}_{\AA^{-3}}$
$\Delta \rho_{\text {min }}=-0.48$ e $\AA^{-3}$

## Special details

Geometry. All esds (except the esd in the dihedral angle between two 1.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Symmetry code: (i) $-x,-y+1,-z+1$.

Hydrogen-bond geometry ( $A,{ }^{\circ}$ )
$C g 1$ is the ring centroid of the $\mathrm{C} 3-\mathrm{C} 8$ ring.
