The reaction of Ni^{II} acetate tetrahydrate with 4-methyl-2-(1,2,3,4-tetrahydronaphthalen-1-ylidene)hydrazinecarbothioamide in a 2:1 molar ratio and recrystallization from dimethylformamide yielded the title compound, [Ni(C₁₂H₁₄N₃S)₂]·C₃H₇NO. The ligands act as monoanionic $\kappa^2 N^1,S$ -donors, forming five-membered metallarings. The Ni^{II} ion is fourfold coordinated in a distorted square-planar *cis*-configuration, which is rather uncommon for monothiosemicarbazone complexes. Intramolecular H···Ni *trans*-interactions are observed [H···Ni distances are 2.50 and 2.57 Å] and thus anagostic interactions can be suggested. The Hirshfeld surface analysis indicates that the major contributions for the crystal packing are H···H (66.6%), H···S (12.3%) and H···C (10.9%) interactions. In the crystal, the complex molecules are linked by dimethylformamide solvent molecules through N—H···O interactions into one-dimensional hydrogen-bonded polymers along [010].

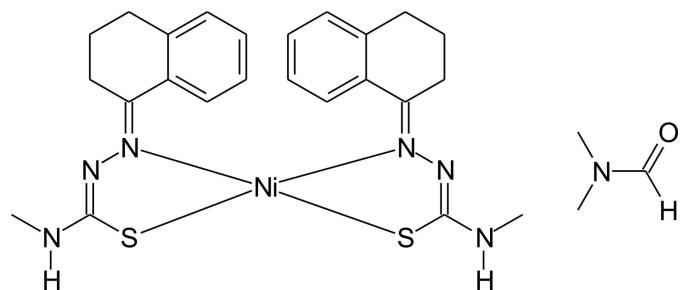

1. Chemical context

One of the first reports on thiosemicarbazone chemistry can be traced back to the beginning of the 20th century in Germany (Freund & Schander, 1902). Initially, thiosemicarbazone derivatives were the products of the identification and characterization reactions of aldehydes and ketones, with thiosemicarbazine as reagent. In the 1940s it was reported that, in *in vitro* assays, thiosemicarbazones turned out to be very effective for the *Mycobacterium tuberculosis* growth inhibition (Domagk *et al.*, 1946) while the synthesis of thiosemicarbazone metal complexes had already been investigated by the early 1950s (Kuhn & Zilliken, 1952). As a result of the main fragment, $R=\text{N}(\text{H})-\text{C}(=\text{S})-\text{NR}_2$, thiosemicarbazone derivatives have a wide range of coordination modes and applications in inorganic chemistry. The hydrazinic H atom can be easily removed and the negative charge is then delocalized over the C—N—N—C—S backbone, which enables chemical bonding with many different metal ions (Lobana *et al.*, 2009). However, a *cis* configuration of the ligated molecules is a rather uncommon coordination mode for mono-thiosemicarbazones and, as far as we know, there is only one Ni^{II} mono-thiosemicarbazone complex reported in

OPEN ACCESS

the literature, with *N*-phenyl-2-(1,2,3,4-tetrahydronaphthalen-1-ylidene)hydrazinecarbothiamide as ligand (for the ligand crystal structure, see: de Oliveira *et al.*, 2014*a*; for the crystal structure of the complex, see: de Oliveira *et al.*, 2014*b*). It can be suggested that the molecular symmetry decreases from a *trans* to a *cis* configuration, possibly by loss of inversion symmetry at the central metal cation, which is compensated for by H \cdots Ni intramolecular interactions and hydrogen-bond formation with solvent molecules. In general, H \cdots metal ion interactions can show covalent or electrostatic character and are observed in some complexes with catalytic applications (Brookhart *et al.*, 2007). As part of our research on the synthesis and structural studies of thiosemicarbazone derivatives, we report herein a new solvated nickel homoleptic complex with the 4-methyl-2-(1,2,3,4-tetrahydronaphthalen-1-ylidene)hydrazinecarbothioamide ligand and dimethylformamide (DMF) as solvent.

2. Structural commentary

One molecule of the title complex and one dimethylformamide solvate comprise the asymmetric unit. The Ni^{II} ion is fourfold coordinated in a distorted square-planar environment by two chelating thiosemicarbazone ligands (Fig. 1).

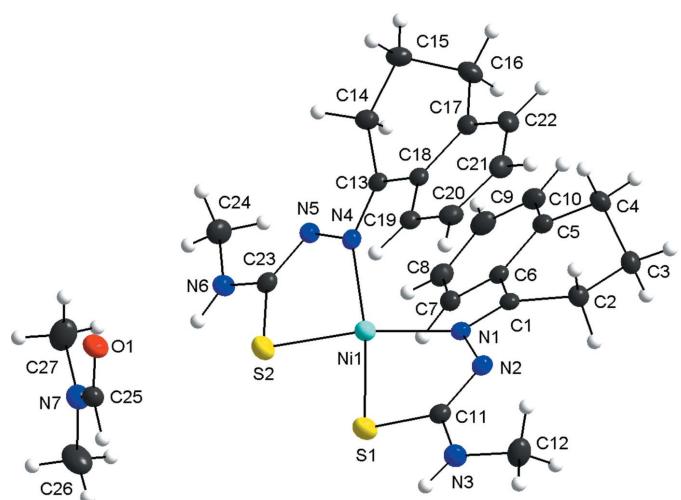

Figure 1

The molecular structure of the title compound and the dimethylformamide solvate, with labelling and displacement ellipsoids drawn at the 40% probability level.

Table 1
Hydrogen-bond geometry (\AA , $^\circ$).

$D-\text{H}\cdots A$	$D-\text{H}$	$\text{H}\cdots A$	$D\cdots A$	$D-\text{H}\cdots A$
N3—H3 \cdots O1 ⁱ	0.88	2.18	2.979 (2)	151
N6—H6 \cdots O1	0.88	2.14	2.875 (2)	140
C7—H7 \cdots Ni1	0.95	2.50	3.0831 (19)	120
C19—H19 \cdots Ni1	0.95	2.57	3.1480 (19)	120

Symmetry code: (i) $-x + 1, y - \frac{1}{2}, -z + \frac{1}{2}$.

The maximum deviation from the Ni1/S1/S2/N1/N4 mean plane amounts to 0.1705 (16) \AA for N1. The S1—Ni1—N4 and S2—Ni1—N1 bond angles are 169.42 (5) and 168.38 (5) $^\circ$, respectively. The distortion along the *trans*-donor atoms confirms the deviation of the coordination sphere from ideal values. Both non-aromatic rings of the tetralone entities have an envelope conformation with maximum deviations from the mean plane of the non-H atoms of 0.3539 (15) \AA for C3 and of 0.3685 (15) \AA for C15. The two ligands are deprotonated with the negative charge delocalized over the C—N—N—C—S entity, as suggested by their intermediate bond lengths and supported by the sp^2 -hybridization for C1, C13, N1, C11, C23 and N4. The imine and thioamide C—N distances indicate considerable double-bond character, while the C—S distance is consistent with mainly single-bond character. The change of the bond lengths is a key feature to distinguish free, *i.e.* non-coordinating, and coordinating thiosemicarbazones. For the title compound these distances (values given in \AA) are C1—N1 = 1.306 (2), N1—N2 = 1.408 (2), N2—C11 = 1.307 (2) and C11—S1 = 1.752 (2) for one ligand and C13—N4 = 1.303 (2), N4—N5 = 1.409 (2), N5—C23 = 1.303 (2) and C23—S2 = 1.7573 (19) for the other one.

The title complex shows two remarkable structural features, namely a *cis* coordination mode, which is rather uncommon for mono-thiosemicarbazone ligands, as well as two positioned

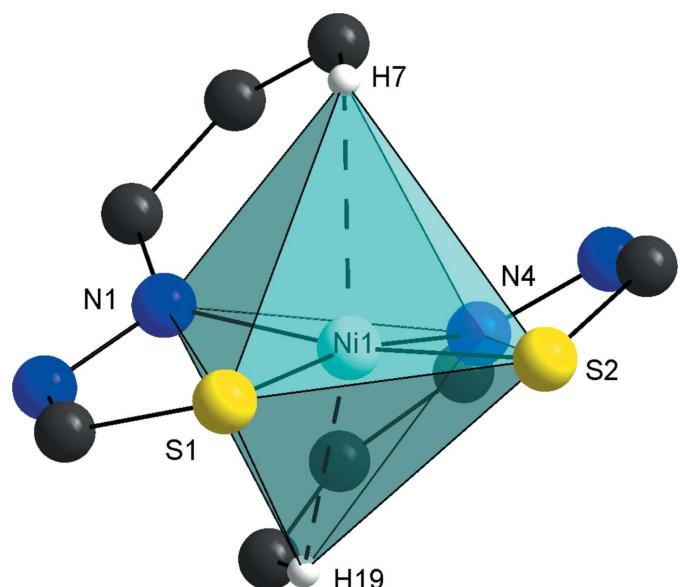

Figure 2

Graphical representation of the metal ion coordination environment, showing the H7 \cdots Ni1 and H19 \cdots Ni1 anagostic interactions as dashed lines. The figure is simplified for clarity.

trans H \cdots Ni anagostic interactions (Fig. 2, Table 1). The H7 \cdots Ni1 and H19 \cdots Ni1 distances are 2.50 and 2.57 Å, being shorter than the sum of the van der Waals radii for H and Ni (2.73 Å; Bondi, 1964; Rowland & Taylor, 1996), in order that electrostatic interactions can be assigned. For an agostic interaction, that involves a covalent or a three-center, two-electron bond, an H \cdots metal distance of at least 2.3 Å is required. The C7–H7 \cdots Ni1 and C19–H19 \cdots Ni1 angles are 120.1 and 119.7°, being in agreement with literature data for another nickel complex with anagostic interactions (de Oliveira *et al.*, 2014*b*).

3. Supramolecular features and Hirshfeld surface analysis

In the crystal, the coordination entities are linked by DMF solvate molecules through N–H \cdots O interactions. The DMF-oxygen atoms are hydrogen-bond acceptors, forming a bridging structure between two N–H \cdots O arrangements: N6–H6 \cdots O1 and N3–H3 \cdots O1ⁱ [symmetry code: (i) $-x + 1$,

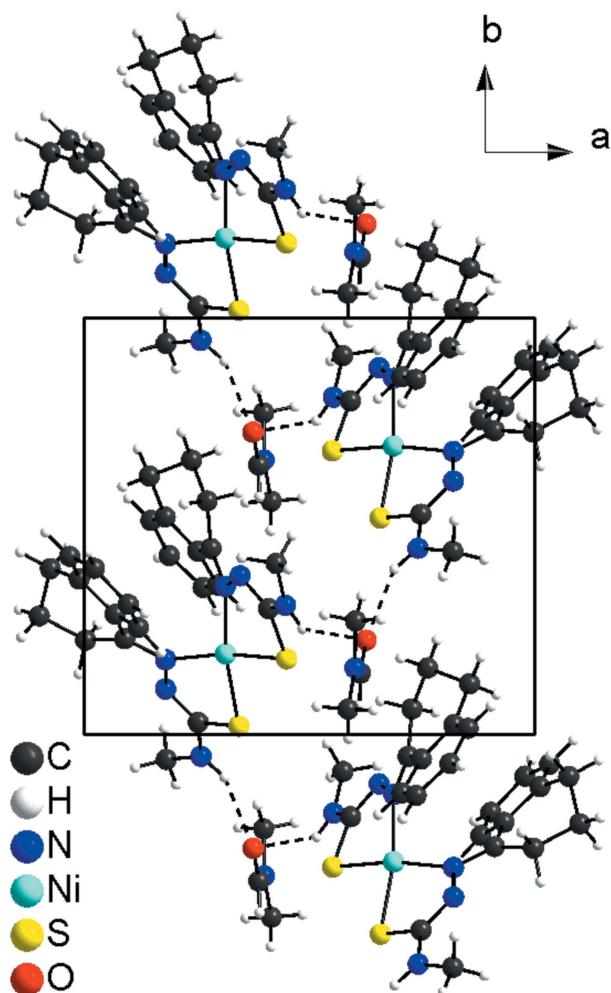

Figure 3

Section of the crystal structure of the title compound viewed along [001], with hydrogen bonds shown as dashed lines (for details, see: Table 1). The figure is simplified for clarity.

$y - \frac{1}{2}, -z + \frac{1}{2}$]. The molecules are linked into one-dimensional hydrogen-bonded polymers along [010] (Fig. 3, Table 1). Additional C–H \cdots O interactions are also present (Table 1).

Hirshfeld (1977) analysis of the crystal structure suggests that the intermolecular H \cdots H interactions contribute 66.6% to the crystal packing, the H \cdots S interactions 12.3% and the H \cdots C interactions 10.9%. Other important intermolecular contacts for the cohesion of the molecules are H \cdots N = 4.5% and H \cdots O = 4.0%. The weak H \cdots Ni interactions contribute by 0.20% to the crystal structure. All contributions to the crystal cohesion are shown as two-dimensional Hirshfeld surface fingerprint plots with cyan dots (Wolff *et al.*, 2012). The d_e (y axis) and d_i (x axis) values are the closest external and internal distances (values in Å) from given points on the Hirshfeld surface contacts (Fig. 4).

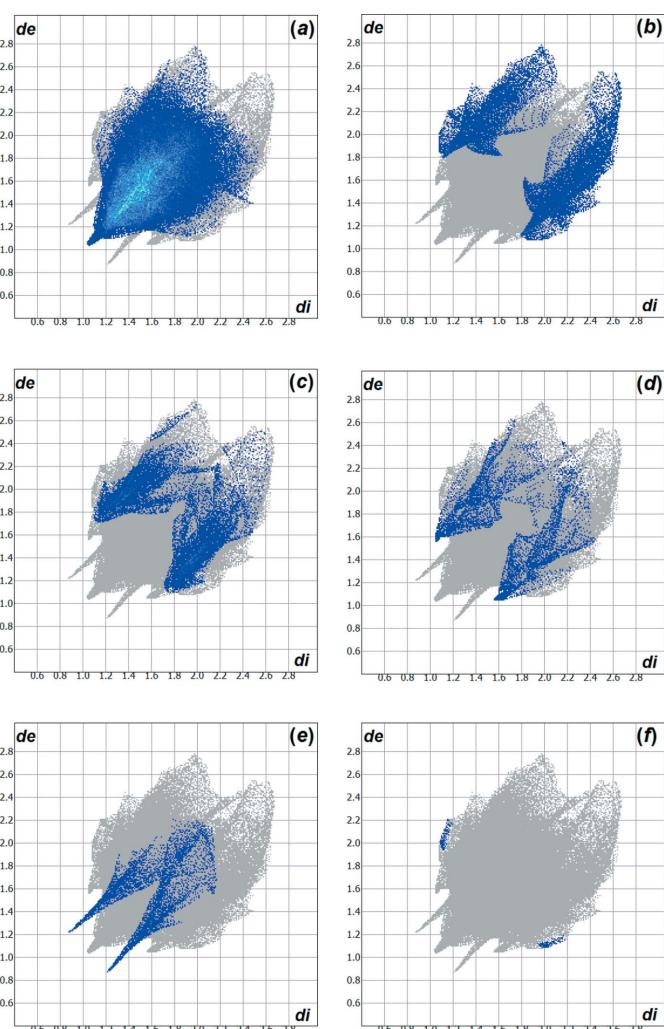

Figure 4

Graphical representation of the two-dimensional Hirshfeld surface fingerprint plots for the interactions in the crystal structure of the title compound. The contacts are drawn in detail (cyan dots) and the contributions to the crystal packing amount to: (a) H \cdots H = 66.6%, (b) H \cdots S = 12.3%, (c) H \cdots C = 10.9%, (d) H \cdots N = 4.5%, (e) H \cdots O = 4.0% and (f) H \cdots Ni = 0.2%. The d_e (y axis) and d_i (x axis) values are the closest external and internal distances (values in Å) from given points on the Hirshfeld surface contacts.

4. Comparison with a related structure

For comparison with the title compound, a literature search revealed only one crystal structure of an Ni^{II}-monothiosemicarbazone complex with *cis* configuration, *viz.* bis{*cis*-(2-(1,2,3,4-tetrahydronaphthalen-1-ylidene)-4-phenyl-hydrazinecarbothioamide- $\kappa^2 N^1, S$)}nickel(II) monohydrate bis(tetrahydrofuran) solvate (de Oliveira *et al.* 2014*b*). The graphical representation of the Hirshfeld surface was performed for the two complexes and suggests, represented in magenta colour, the locations of the strongest intermolecular contacts (Fig. 5). Both structures have the same main fragment for the ligand, the α -tetralone-thiosemicarbazone, anagostic H...Ni intramolecular interactions and hydrogen bonding with the solvate molecules, suggesting the stabilization of the crystal packing, since the *cis* configuration implies a symmetry decrease with loss of the inversion center and appears to be energetically unfavourable.

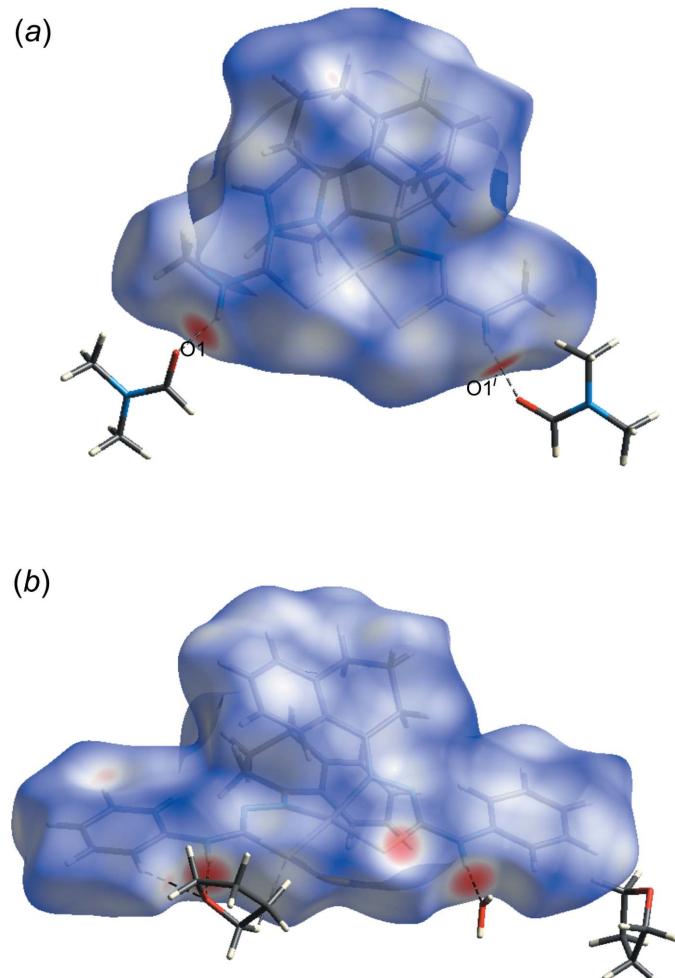

Figure 5

The Hirshfeld surface graphical representation (d_{norm}) for: (a) the asymmetric unit of the title compound and (b) the asymmetric unit of the comparison compound, bis{*cis*-(2-(1,2,3,4-tetrahydronaphthalen-1-ylidene)-4-phenyl-hydrazinecarbothioamide- $\kappa^2 N^1, S$)}nickel(II) monohydrate bis(tetrahydrofuran) solvate (de Oliveira *et al.* 2014*b*). The surface regions with the strongest intermolecular interactions are drawn in magenta. The figure is simplified for clarity. [Symmetry code: (i) $-x + 1, y - \frac{1}{2}, -z + \frac{1}{2}$]

5. Synthesis and crystallization

Starting materials were commercially available and were used without further purification. The synthesis of the ligand was adapted from a procedure reported previously (Freund & Schander, 1902) with 1-tetralone and 4-methylthiosemicarbazide. 2-(1,2,3,4-Tetrahydronaphthalen-1-ylidene)-4-methyl-hydrazinecarbothioamide was dissolved in tetrahydrofuran (THF; 2 mmol / 40 ml) with stirring maintained for 30 min until the solution turned yellow. At the same time, a green solution of nickel acetate tetrahydrate in THF (1 mmol / 40 ml) was prepared under continuous stirring. A dark coloured mixture of both solutions was maintained with stirring at room temperature for 6 h. A crude dark red material was obtained by evaporation of the solvent. Dark red crystals of the complex, suitable for X-ray analysis, were obtained by recrystallization of the solid from a dimethylformamide solution.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. All H atoms were located in difference maps but were positioned with idealized geometry and were refined using a riding model with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C and N})$ for the sp^2 -hybridized DMF C atom, the aromatic and the secondary C atoms, and for all N atoms, and with $U_{\text{iso}}(\text{H}) =$

$1.5U_{\text{eq}}(\text{C})$ for the methyl C atoms. The bond lengths (values given in Å) are: C—H = 0.99 for $-\text{CH}_2-$ fragments, C—H = 0.98 for CH_3- fragments, C—H = 0.95 for aromatic groups and the sp^2 -hybridized DMF C atom; N—H = 0.88 for all N atoms.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
