The title compound, $[Cd_2(C_7H_{10}NS_2)_4]$, is a neutral dinuclear cadmium(II) complex bearing four bis *N,N*-diallyldithiocarbamate ligands coordinating to two Cd^{II} cations. In each of the monomeric subunits, there are four S atoms of two dithiocarbamate ligands [Cd—S = 2.5558 (3), 2.8016 (3), 2.6050 (3) and 2.5709 (3) Å] that coordinate to one Cd^{II} atom in a bidentate mode. The dimers are located over an inversion centre bridged by two additional bridging Cd—S bonds [2.6021 (3) Å], leading to a substantial distortion of the geometry of the monomeric subunit from the expected square-planar geometry. The five-coordinate environment around each of the Cd^{II} ions in the dimer is best described as substantially tetragonally distorted square pyramidal. The dithiocarbamate groups are themselves planar and are also coplanar with the Cd^{II} ions. The negative charge on these groups is delocalized by resonance across the S atoms bound to the Cd^{II} cation. This delocalization of the π electrons in the dithiocarbamate groups also extends to the C—N bonds as they reveal significant double bond character [C—N = 1.3213 (16) and 1.3333 (15) Å].

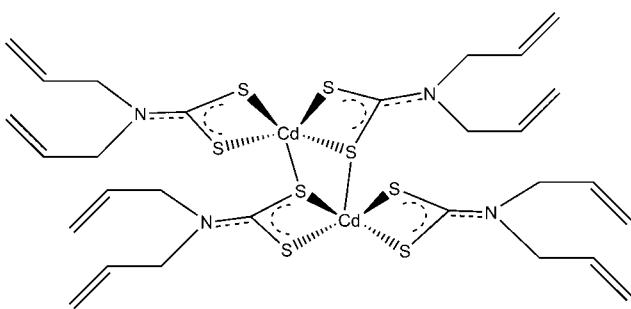

1. Chemical context

Interest in the study of metal dithiocarbamates was aroused because of their interesting structural features and diverse applications (Thammakan & Somsook, 2006). Dithiocarbamate complexes have largely been prepared from the group 12 elements, mostly because they have found wide practical application as additives to pavement asphalt, as antioxidants, and as potent pesticides *etc* (Subha *et al.*, 2010). The structural chemistry of cadmium dithiocarbamates of the general formula Cd(S₂CNRR') where R, R' = alkyl or aryl is dominated by its existence in binuclear form. This common feature has been ascribed to the effect of aggregated species, which they adopt in the solid state, resulting from equal numbers of μ_2 -tridentate and bidentate (chelating) ligands (Tiekink, 2003; Tan, Halim *et al.*, 2016). Only a few exceptions have been reported where the complex exists in a trinuclear form (Kumar *et al.*, 2014), or as a one-dimensional polymeric motif (Tan *et al.*, 2013, 2016; Ferreira *et al.*, 2016). Bis(*N,N*-diallyldithiocarbamato)cadmium compounds have the advantage of having stability similar to that of the zinc complexes, but more favourable stability when compared to the mercury complexes. Cadmium dithiocarbamate complexes have been widely used as single-source precursors for CdS

OPEN ACCESS

nano-particles and thin films, which have application as non-linear optical materials (Thammakan & Somsook, 2006). Another important practical application of cadmium dithiocarbamates is their ability to efficiently collect gold from acidic solutions (Rodina *et al.*, 2014). Here we describe the crystal structure of a Cd^{II} complex bearing a diallyldithiocarbamate ligand in a chelating and bridging dimeric structure.

2. Structural commentary

The coordination environment of the Cd^{II} cation is observed to have a distorted tetragonal-pyramidal geometry (Fig. 1). The Cd^{II} cation is coordinated by four S atoms with distances ranging from 2.5558 (3) to 2.8016 (3) Å and to a fifth S atom at a distance of 2.6021 (3) Å; these distances are similar to other complexes found to have been published previously (see Section 4: *Database survey*). A full geometry check carried out with the *Mogul* Geometry Check tool (Bruno *et al.*, 2004) within the CSD suite of programs, showed no unusual geometrical parameters. The fifth S atom, S12ⁱ, is from a third ligand that is in the coordination sphere of a centrosymmetrically related Cd^{II} ion [symmetry code: (i) $-x + 2, -y, -z + 1$]. This means that each bridging S atom simultaneously occupies an equatorial coordination site on one Cd^{II} ion and an apical site on the other Cd^{II} ion to form an edge-shared tetragonal-pyramidal geometry. The Cd^{II} ion deviates from the S11–S12–S22–S21 mean plane by 0.704016 (17) Å towards S12ⁱ. The bridging network Cd1–S12–Cd1ⁱ–S12ⁱ is completely

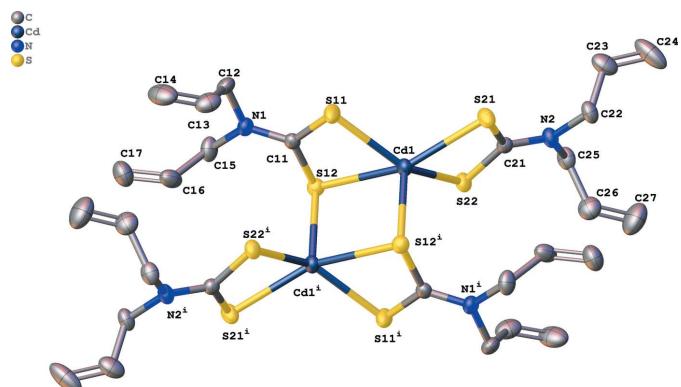

Figure 1

Table 1
Selected geometric parameters (Å, °).

Cd1–S11	2.5558 (3)	S12–C11	1.7532 (13)
Cd1–S22	2.5709 (3)	S21–C21	1.7224 (12)
Cd1–S12 ⁱ	2.6021 (3)	S22–C21	1.7263 (12)
Cd1–S21	2.6050 (3)	N1–C11	1.3213 (16)
Cd1–S12	2.8016 (3)	N2–C21	1.3333 (15)
S11–C11	1.7162 (13)		
S11–Cd1–S22	143.705 (13)	S22–Cd1–S12	96.950 (10)
S11–Cd1–S21	108.203 (11)	S12 ⁱ –Cd1–S12	96.257 (9)
S22–Cd1–S21	70.264 (10)	S21–Cd1–S12	152.651 (11)
S11–Cd1–S12	67.486 (10)	Cd1 ⁱ –S12–Cd1	83.743 (9)

Symmetry code: (i) $-x + 2, -y, -z + 1$.

planar since it lies over the inversion centre with a Cd1–Cd1ⁱ separation distance of 3.60987 (8) Å and S12–Cd1–S12ⁱ and Cd1–S12–Cd1ⁱ angles of 96.257 (9) and 83.743 (9)°, respectively. There is substantial distortion of the geometry of the monomeric subunit from the expected square-planar geometry. Deviations from the standard 90° angles are evident in the angles of S11–Cd1–S21 [108.203 (11)°]; S22–Cd1–S21 [70.264 (10)°]; S22–Cd1–S12 [96.950 (10)°] and S11–Cd1–S12 [67.486 (10)°]. Deviations in the standard 180° angles are evident in the angles of S11–Cd1–S22 [143.705 (13)°] and S21–Cd1–S12 [152.651 (11)°]. The Cd1–S12–Cd1ⁱ–S12ⁱ and S11–S12–S22–S21 mean planes form a dihedral (twist) angle of 84.6228 (18)°. The dithiocarbamate groups are planar and each group of the monomeric subunit is coplanar with the Cd^{II} ion (r.m.s. deviation is 0.010 Å). The mean plane consisting of atoms Cd1, S11, N1, C11, S12 and the mean plane consisting of atoms Cd1, S22, N2, C21, S21 have a plane-normal-to-plane-normal angle of 37.0291 (10)°; a centroid-to-centroid distance of 4.45354 (8) Å; a plane-to-plane shift of 4.22298 (8) Å and a plane-to-plane torsion (twist) angle of 8.0304 (12)°.

The S12–C11 bond length [1.7532 (13) Å] is longer than the adjacent S11–C11 bond length [1.7162 (13) Å] suggesting that this bond has more double bond character in the dithiocarbamate portion that coordinates to the Cd^{II} cation. On the opposite side of the Cd^{II} ion, both S–C bonds have approximately the same length, where S21–C21 and S22–C21 bond lengths are 1.7224 (12) and 1.7263 (12) Å, respectively, suggesting that the double bond of the dithiocarbamate is spread over the S–C–S bond *via* resonance. A possible explanation for this may be because of the fact that atom S12 serves as the bridging S atom in the complex. Also, the N1–C11 and N2–C21 distances [1.3213 (16) and 1.3333 (15) Å, respectively] are shorter compared to the other N–C distances indicating considerable double-bond character. The vinyl substituents are also planar and are at an angle of 91.6049 (14)° from the dithiocarbamate plane and at an angle of 150.9196 (6)° from the vinyl group directly opposite from it. This scenario is comparable with the other structures surveyed in the literature (see Section 4: *Database survey*). All highlighted and discussed geometrical parameters describing the coordination environment are given in Table 1. Weak intra-molecular C–H···S interactions are observed (Table 2).

3. Supramolecular features

The space group of the crystal is $P\bar{1}$, and the asymmetric unit consists of one-half of the complex molecule, so that the unit cell contains one complete complex molecule. Each half of the asymmetric unit is related by an inversion centre. In the crystal, weak C—H···π interactions are observed, forming chains along [001] (see Fig. 2 and Table 3).

4. Database survey

A search of the Cambridge Structural Database (version 1.19, May 2017 updates) (Groom *et al.*, 2016) revealed that there are a number of similar types of compounds where in place of the *N,N*-dialyl side chain, the side-chains substituents are di-n-propyl [CSD refcodes BEHNOR (Jian *et al.*, 1999a),

BEHNOR01 (Ivanov *et al.*, 2005)], di-isobutyl [LESVEK (Cox & Tiekkink, 1999), LESVEK01 (Glinskaya *et al.*, 1999)] and di-isopropyl [SUVTUY (Jian *et al.*, 1999b), SUVTUY01 (Cox & Tiekkink, 1999)].

5. Synthesis and crystallization

A solution of $\text{CdCl}_2 \cdot 2\text{H}_2\text{O}$ (0.55 g, 0.0025 mol) in ethanol (10 ml) was added to a solution of sodium *N,N*-dialyl dithiocarbamate (0.98 g, 0.005 mol) in ethanol (10 ml), and the resulting suspension was stirred for 45 min at room temperature. This solution was then filtered, and rinsed several times with distilled water (Onwudiwe *et al.*, 2015) and ethanol. Yield: 1.28 g, 56%. Analysis found: C, 36.38; H, 4.40; N, 6.50; S, 28.42%. Calculated for $\text{C}_{14}\text{H}_{20}\text{N}_2\text{S}_4\text{Cd}$: C, 36.79; H, 4.41; N, 6.13; S, 28.06. Crystals suitable for single-crystal X-ray analysis were obtained by recrystallization from chloroform/ethanol. Other analytical data for this material (melting point, IR and

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4. All H atoms were positioned geometrically and refined isotropically using the riding-model approximation with C—H = 0.99 Å and $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$ for methylene groups and C—H = 0.95 Å and $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$ for all vinyl groups.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Carbon-bound H atoms were placed in calculated positions and were included in the refinement in the riding model approximation, with $U(H)$ set to 1.2 $U_{eq}(C)$.

Two reflections with large differences between their observed and calculated intensity were omitted. This is probably due to obstruction by the beam stop.
