The crystal structures of bis{3,5-difluoro-2-[4-(2,4,6-trimethylphenyl)pyridin-2-yl]phenyl- κ^2N,C^1 }(picolinato- κ^2N,O)iridium(III), [Ir(C₂₀H₁₆F₂N)₂(C₆H₄NO₂)], **1**, and bis[2-(4-*tert*-butylpyridin-2-yl)-3,5-difluorophenyl- κ^2N,C^1](picolinato- κ^2N,O)iridium(III), [Ir(C₁₅H₁₄F₂N)₂(C₆H₄NO₂)], **2**, are presented herein. These phosphorescent cyclometallated iridium(III) compounds have been structurally investigated in order to better understand the nature of their blue-shifted emissions while maintaining high quantum yields. Compound **1** exhibits substantial twisting of the mesitylene rings out of the plane of the attached pyridine ring, with dihedral angles of 67.0 (1) and 78.7 (1) $^\circ$ between the best mean planes. For both compounds, the contribution of disordered solvent molecule(s) was removed using the SQUEEZE [Spek (2015). *Acta Cryst. C*71, 9–18] routine in PLATON [Spek (2015). *Acta Cryst. C*71, 9–18]. These solvent molecules are not considered in the given chemical formula and other crystal data.

1. Chemical context

Phosphorescent cyclometallated iridium(III) compounds have been investigated for a variety of applications, including solar cells (Kim *et al.*, 2016), sensors (Marín-Suárez *et al.*, 2012), bioimaging (Zhang *et al.*, 2015), and scintillators (Bertrand *et al.*, 2015). However, their most widespread use stems from their electrophosphorescence and research in this area has focused on their use in organic light-emitting diodes (OLED) (Choy *et al.*, 2014; Chi & Chou, 2010; Fu *et al.*, 2011). The most widely studied blue-emitting iridium complex for this purpose is bis[2-(4,6-difluorophenyl)pyridinato]iridium(III) picolinate, or FIripic (Baranoff & Curchod, 2015). As part of our synthesis program for plastic scintillators (Rupert *et al.*, 2012; Cherepy *et al.*, 2015), we have prepared and structurally characterized several blue-emitting iridium complexes (Sanner *et al.*, 2016). A recent study by another group has examined the attachment of alkyl or aryl groups to the pyridine ring of the (difluorophenyl)pyridinate ligand in FIripic (Kozhevnikov *et al.*, 2013), resulting in enhanced quantum efficiency, while maintaining the sky-blue color of the parent complex. We have prepared and structurally characterized two of those complexes to examine the structural basis for their superior behavior. We report herein the crystal structures of bis{3,5-difluoro-2-[4-(2,4,6-trimethylphenyl)pyridin-2-yl]phenyl- κ^2N,C^1 }(picolinato- κ^2N,O)iridium(III), **1**, and bis[2-(4-*tert*-butylpyridin-2-yl)-3,5-difluorophenyl- κ^2N,C^1](picolinato- κ^2N,O)iridium(III), **2**. The molecular structure of **2** has been reported previously (Laskar *et al.*, 2006), however, the structure reported below is a new polymorph.

OPEN ACCESS

2. Structural commentary

The molecular structure of complexes **1** and **2** have been confirmed by X-ray crystallography and displacement ellipsoid diagrams are shown in Figs. 1 and 2. Both complexes exhibit the same distorted octahedral geometry with two bidentate phenylpyridine ligands (coordinated through the pyridine N atom and a phenyl C atom) and one bidentate pyridine-2-carboxylate ligand, also known as 2-picoline (coordinated through the pyridine N atom and a carboxylate O atom). The iridium-bound N atoms of the phenylpyridine ligands are *trans* to each other, while the phenyl C atoms bound to iridium are *cis*. The two ligated atoms in the picolinate ligand are then *trans* to the phenyl C atoms of the phenylpyridine ligand. The *trans* effect of the phenyl groups is most clearly seen when comparing Ir–N bond lengths. Thus, the Ir–N(picolinate) bond is on average 0.1 Å longer than the Ir–N(phenylpyridine) bond due to its *trans* disposition to the phenyl group. Although there is no such intramolecular comparison available for the picolinate Ir–O bond (which is also *trans* to a phenyl group), we note that the Ir–O bond length in both these molecules is 2.16 Å. This compares with the shorter value of 2.09 Å reported in the Cambridge Structural Database (CSD; Version 5.39, May 2018, with three updates; Groom *et al.*, 2016) for an Ir–O bond, again illustrating the *trans* effect of the phenyl group in these molecules. The C–Ir–N ‘bite’ angle for the phenylpyridine ligand averages 80.8 (4)° for these complexes, while the N–Ir–O angle for the picolinate ligand is somewhat smaller at 76.7 (2)°. The phenyl and pyridine rings in each phenylpyridine ligand are slightly twisted with respect to each other across the C–C bond linking the two rings. The dihedral angle between the best planes for the two rings is in the range 6–10° in these

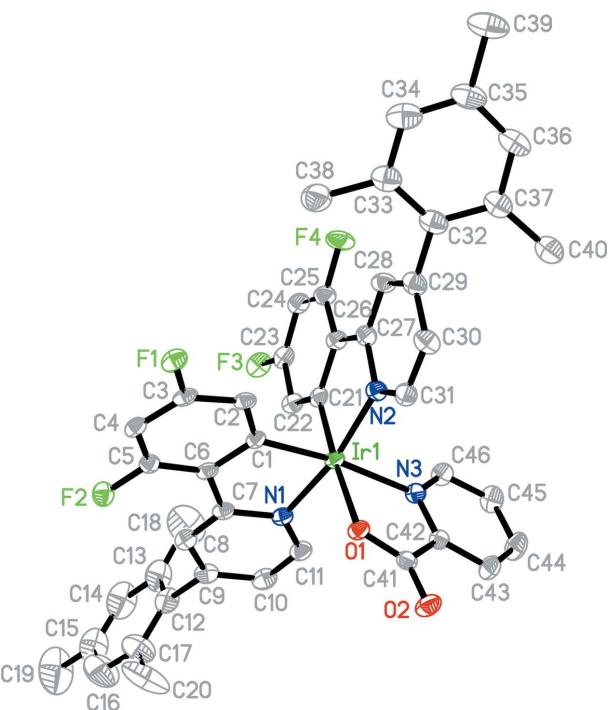

Figure 1

molecules. A feature of special interest in **1** is the dihedral angle between the plane of the pyridine ring and that of the attached mesityl group, *e.g.* between the N1/C7–C11 ring and the C12–C17 ring. These values are 67.0 (1) and 78.7 (1)° for the two mesityl–phenylpyridine ligands in **1**. The presence of two *ortho*-methyl groups on the mesitylene (*e.g.* C18 and C20) presumably causes this large twist of the mesitylene ring out of the

plane of the attached pyridine ring. This possibility has been proposed (Kozhevnikov *et al.*, 2013) as an explanation for the blue emission of **1** since it minimizes the π-conjugation between the mesityl and pyridine rings which would otherwise lead to red-shifted emission. Our results confirm the structural basis for this proposal.

3. Supramolecular features

Neither complex forms any significant supramolecular interactions with neighboring molecules.

4. Database survey

The molecular structure of **2** has been reported previously (Laskar *et al.*, 2006; CSD refcode CEHGOM); however, the structure reported below is a new polymorph as a solvate. A search of the CSD (Groom *et al.*, 2016) provided no additional crystal structures related to **1** or **2**.

5. Synthesis and crystallization

The title compounds were prepared as described previously (Kozhevnikov *et al.*, 2013). Diffraction-quality crystals of **1** were obtained by slow evaporation using methanol as solvent, while **2** utilized a 1:2 (v/v) methyl ethyl ketone–hexane mixture as solvent.

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 1. All H atoms were placed in calculated positions and refined as riding atoms; for aryl H atoms, C—H = 0.95 Å and *U*_{iso}(H) = 1.2*U*_{eq}(C), and for methyl H atoms, C—H = 0.98 Å and *U*_{iso}(H) = 1.5*U*_{eq}(C). Both specimens used for this study contained badly disordered solvent of crystallization. Specimens for compound **1** tended to lose solvent during mounting. The initial structure solution appeared to be either a methanol trisolvate or a methanol/water disolvate, where all three molecules were concatenated through hydrogen bonds to the O₂ hydrogen-bond acceptor. Only one methanol solvent molecule was clearly indicated, but it had considerable translational displacements toward a putative compositionally disordered methanol/water site. The last member of this chain was likely a methanol, but it was pathologically disordered. The SQUEEZE routine (Spek, 2015) from PLATON (Spek, 2009) was applied to this disordered solvent region since in least-squares no reasonable disorder model could be achieved. Void spaces centered at (0, 0, 0) and (0, 0.5, 0.5) totaling 727 Å³ were found to contain an electron count of 177. This electron count would correspond to approximately ten methanol molecules per unit cell. The specimen for compound **2** did not appear to lose solvent during mounting. The initial structure solution found the expected compound and a region near an inversion center composed of unknown solvent. The peaks in the difference Fourier map did not provide any reasonable solvent molecule (or molecules) after numerous attempts. The SQUEEZE

routine from *PLATON* was applied to this disordered solvent region. Void spaces centered at (0, 0, 0.5) and (0, 0.5, 0) totaling 954.7 Å³ were found to contain an electron count of 203. This electron count would correspond to approximately four methyl ethyl ketone or hexane molecules per unit cell.

Acknowledgements

We thank the X-Ray Crystallographic Laboratory, LeClaire-Dow Instrumentation Facility, Department of Chemistry, University of Minnesota, for its contribution. The authors would like to acknowledge Mr James T. Moore and the X-Ray Crystallography course CHEM5755 for assistance in collecting single-crystal diffraction data on **1** and **2**. The Bruker AXS D8 Venture diffractometer was purchased through a grant from NSF/MRI and the University of Minnesota.

Funding information

Funding for this research was provided by: US DOE, Lawrence Livermore National Laboratory (contract No. DE-AC52-07NA27344); US DOE, National Nuclear Security Administration, Defense Nuclear Non-proliferation Research and Development (contract No. DE-AC03-76SF00098); NSF/MRI (award No. 1229400).

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Cell parameters from 2779 reflections

 $\theta = 2.8\text{--}30.1^\circ$ $\mu = 3.55 \text{ mm}^{-1}$ $T = 100$ K

Plate, yellow

0.15 × 0.13 × 0.04 mm

Data collection

Area Bruker PHOTON-II CPAD
diffractometer
Radiation source: microfocus
 φ and ω scans
Absorption correction: multi-scan
(SADABS; Bruker, 2014)
 $T_{\min} = 0.370$, $T_{\max} = 0.433$
81284 measured reflections

11662 independent reflections
9342 reflections with $I > 2\sigma(I)$
 $R_{\text{int}} = 0.049$
 $\theta_{\max} = 30.6^\circ$, $\theta_{\min} = 2.4^\circ$
 $h = -21 \rightarrow 21$
 $k = -20 \rightarrow 20$
 $l = -26 \rightarrow 19$

Refinement

Refinement on F^2
Least-squares matrix: full
 $R[F^2 > 2\sigma(F^2)] = 0.025$
 $wR(F^2) = 0.057$
 $S = 1.02$
11662 reflections
421 parameters
0 restraints

Hydrogen site location: inferred from
neighbouring sites
H-atom parameters constrained
 $w = 1/[\sigma^2(F_o^2) + (0.0242P)^2 + 2.756P]$
where $P = (F_o^2 + 2F_c^2)/3$
 $(\Delta/\sigma)_{\max} = 0.002$
 $\Delta\rho_{\max} = 0.98 \text{ e } \text{\AA}^{-3}$
 $\Delta\rho_{\min} = -1.39 \text{ e } \text{\AA}^{-3}$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters (\AA^2)
