The quaternary thiogermanates  $\text{Cu}_4\text{FeGe}_2\text{S}_7$  (tetracopper iron digermanium heptasulfide) and  $\text{Cu}_4\text{CoGe}_2\text{S}_7$  (tetracopper cobalt digermanium heptasulfide) were prepared in evacuated fused-silica ampoules *via* high-temperature, solid-state synthesis using stoichiometric amounts of the elements at 1273 K. These isostructural compounds crystallize in the  $\text{Cu}_4\text{NiSi}_2\text{S}_7$  structure type, which can be considered as a superstructure of cubic diamond or sphalerite. The monovalent ( $\text{Cu}^+$ ), divalent ( $\text{Fe}^{2+}$  or  $\text{Co}^{2+}$ ) and tetravalent ( $\text{Ge}^{4+}$ ) cations adopt tetrahedral geometries, each being surrounded by four  $\text{S}^{2-}$  anions. The divalent cation and one of the sulfide ions lie on crystallographic twofold axes. These tetrahedra share corners to create a three-dimensional framework structure. All of the tetrahedra align along the same crystallographic direction, rendering the structure non-centrosymmetric and polar (space group  $C2$ ). Analysis of X-ray powder diffraction data revealed that the structures are the major phase of the reaction products. Thermal analysis indicated relatively high melting temperatures, near 1273 K.

## 1. Chemical context

The title compounds belong to the family of quaternary thiogermanates, which can be constructed from different  $[\text{Ge}_x\text{S}_y]^{z-}$  building blocks, such as  $[\text{GeS}_4]^{4-}$  (Aitken *et al.*, 2001) and  $[\text{Ge}_2\text{S}_6]^{4-}$  (Choudhury *et al.*, 2015). Two  $\text{GeS}_4$  tetrahedra can share a corner to create  $[\text{Ge}_2\text{S}_7]^{6-}$  units, which are featured in the title compounds.  $\text{Cu}_4\text{FeGe}_2\text{S}_7$  and  $\text{Cu}_4\text{CoGe}_2\text{S}_7$  also belong to the family of diamond-like semiconductors (DLSs), with structures that can be derived from the cubic or hexagonal (Frondel & Marvin, 1967) forms of diamond. The synthesis of new diamond-like materials is guided by valence electron principles and Pauling's rules, and the resulting DLSs can be binary, ternary, or quaternary, depending on the number of elements employed in the reaction (Parthé, 1964; Pamplin, 1981; Goryunova, 1965). Increasing the number of elements in the formula allows for greater tunability of the material's properties; thus, quaternary DLSs are a particularly appealing class of materials. As a result of their technologically relevant properties, these materials are of interest for a number of applications, such as solar cells (Ito & Nakazawa, 1988; Hepke *et al.*, 2020; Liu *et al.*, 2018), batteries (Brant, Devlin *et al.*, 2015; Kaib *et al.*, 2013) and magnetic devices (Wintenberger, 1979; Greenwood & Whitfield, 1968). Furthermore, owing to their inherently non-centrosymmetric structures, DLSs are attractive candidates for infrared non-linear optical (IR-NLO) devices that make use of second-harmonic generation (SHG) crystals (Ohmer & Pandey 1998): only crystals that lack an inversion center can exhibit SHG.

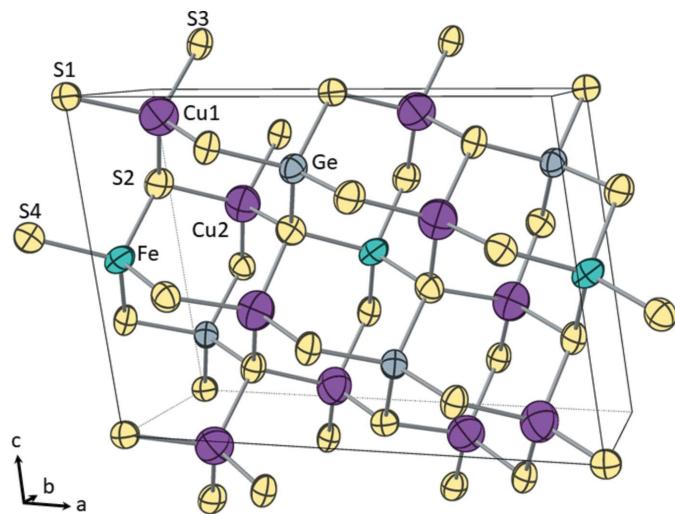

OPEN ACCESS

IR-NLO materials are used to shift the radiation of lasers to more suitable wavelengths for use in military (Hopkins 1998), medical (Stoeppeler *et al.*, 2012) and industrial applications (Bamford *et al.*, 2007). Currently, ternary DLSs, most of which are sulfides, dominate the market of SHG crystals for use in the infrared (Ohmer & Pandey, 1998). Yet the current commercially available IR-NLO materials suffer from serious drawbacks, such as low laser-induced damage thresholds (LIDTs) and multi-photon absorption (Schunemann, 2007). Turning attention to the discovery of new quaternary DLSs provides a reliable route to next-generation IR-NLO materials that allows for greater control of the material's properties. Compounds such as  $\text{Li}_2\text{CdGeS}_4$  (Brant, Clark *et al.*, 2014),  $\text{Li}_2\text{MnGeS}_4$  (Brant, Clark *et al.*, 2015), and  $\text{Li}_4\text{HgGe}_2\text{S}_7$  (Wu, Yang & Pan, 2017) have shown potential to outperform currently used ternary IR-NLO crystals. These DLSs have shown promising SHG capabilities, as well as resilience to high powered lasers, a necessity to broaden future usage (Hopkins, 1998). For these reasons, we were motivated to investigate the Cu–Fe–Ge–S and Cu–Co–Ge–S systems for new DLSs.

## 2. Structural commentary

The title compounds,  $\text{Cu}_4\text{FeGe}_2\text{S}_7$  (I) and  $\text{Cu}_4\text{CoGe}_2\text{S}_7$  (II), are isostructural and crystallize in the non-centrosymmetric, monoclinic space group  $C2$  (No. 5) with the  $\text{Cu}_4\text{NiSi}_2\text{S}_7$  structure type (Schäfer *et al.*, 1980). The structure contains two crystallographically unique  $\text{Cu}^+$  ions, one divalent metal (Fe or Co) sited on a crystallographic twofold axis, one  $\text{Ge}^{4+}$  cation and four  $\text{S}^{2-}$  anions (one with site symmetry 2) (Fig. 1). The sulfide anions create a ‘cubic’ close-packed array and the cations reside in one-half of the tetrahedral holes; these tetrahedra share corners to form a three-dimensional network. Two  $\text{GeS}_4$  tetrahedra share corners to form  $(\text{Ge}_2\text{S}_7)^{6-}$  subunits that are isolated from each other (Fig. 1). These subunits are separated by isolated  $\text{FeS}_4$  tetrahedra and surrounded by a

**Figure 1**

The structure of  $\text{Cu}_4\text{FeGe}_2\text{S}_7$  with crystallographically unique ions labeled. Ellipsoids are shown at 99% probability.  $\text{Cu}_4\text{CoGe}_2\text{S}_7$  is isostructural and has similar atomic displacement parameters.

snaking, three-dimensional network of corner-sharing  $\text{CuS}_4$  tetrahedra that serve to link the  $(\text{Ge}_2\text{S}_7)^{6-}$  and  $\text{FeS}_4$  subunits. All of the tetrahedra are aligned along one crystallographic direction, rendering the structure non-centrosymmetric (Fig. 2). All DLSs exhibit a honeycomb pattern in their crystal structure (Fig. 3); the various resulting space groups arise from the different possible cation-ordering patterns.

Selected geometrical data for (I) and (II) are given in Tables 1 and 2, respectively. The average  $\text{Fe-S}$  (I) and  $\text{Co-S}$  (II) bond distances are 2.334 (6) and 2.317 (6)  $\text{\AA}$ , respectively. These values align well with other compounds containing iron or cobalt tetrahedrally coordinated by sulfur. For example, the average  $\text{Fe-S}$  distance found in  $\text{Li}_2\text{FeGeS}_4$  is 2.34 (2)  $\text{\AA}$ .

**Figure 2**  
Polyhedral view of  $\text{Cu}_4\text{FeGe}_2\text{S}_7$  showing the polar nature of the structure.

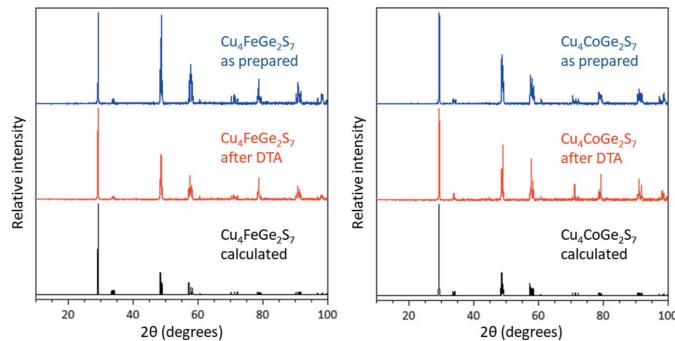

**Figure 3**

The ‘honeycomb’ pattern found in  $\text{Cu}_4\text{FeGe}_2\text{S}_7$ , a characteristic of DLSs. Highlighted in the bottom left corner is one of the  $[\text{Ge}_2\text{S}_7]^{6-}$  subunits that forms in this structure.

(Brant, dela Cruz *et al.*, 2014), while the average Co–S distance found in  $\text{Li}_2\text{CoGeS}_4$  is 2.31 (3) Å (Brant, Devlin *et al.*, 2015). The average Ge–S distances are 2.240 (4) and 2.244 (5) Å for (I) and (II), respectively. These distances are also close to those of the lithium-containing DLSs:  $\text{Li}_2\text{FeGeS}_4$  (Brant, Devlin *et al.*, 2015) and  $\text{Li}_2\text{CoGeS}_4$  (Brant, dela Cruz *et al.*, 2014) possess values of 2.23 (2) and 2.22 (3) Å, respectively. The average tetrahedral bond angles for all cations in both title compounds is, within uncertainty, ideal. For comparison, the tetrahedral angular ranges encountered in  $\text{Cu}_2\text{FeGeS}_4$  (Wintenberger, 1979) and  $\text{Cu}_2\text{CoGeS}_4$  (Gulay *et al.*, 2004) are 109.471–109.484° and 109.473–109.579°, respectively. The sulfur anions also exhibit tetrahedral coordination. Both S2 and S4 are coordinated by two copper, one germanium and one iron or cobalt cation. S1 is connected to two germanium and two copper cations, while S3 is surrounded by one germanium and three copper cations.

### 3. Database survey

Quaternary DLSs exist with several different formulae; examples that incorporate chalcogenides as the anion are I–II<sub>2</sub>–III–VI<sub>4</sub>, I<sub>2</sub>–II–IV–VI<sub>4</sub>, and I<sub>4</sub>–II–IV<sub>2</sub>–VI<sub>7</sub>. In these formulae, the Roman numerals represent the number of valence electrons for each element. Compounds of the formula I–II<sub>2</sub>–III–VI<sub>4</sub>, such as  $\text{CuMn}_2\text{InS}_4$  (Delgado & Sagredo, 2016) and  $\text{CuFe}_2\text{InSe}_4$  (Delgado *et al.*, 2008) include trivalent elements, while the other relevant formulae mentioned above, including the title compounds, contain

**Figure 4**

Comparison of experimental X-ray powder diffraction patterns before and after DTA with those calculated using the single-crystal structures for  $\text{Cu}_4\text{FeGe}_2\text{S}_7$  (left) and  $\text{Cu}_4\text{CoGe}_2\text{S}_7$  (right).

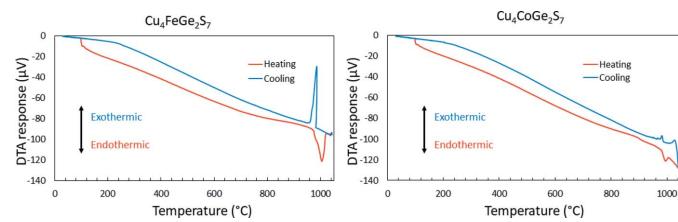

tetravalent elements. Numerous DLSs of the general formula I<sub>2</sub>–II–IV–VI<sub>4</sub> have been reported and crystallize in non-centrosymmetric space groups, such as  $\overline{1}42m$  and  $Pmn2_1$  with the stannite and wurtz-stannite structure types that are derived from the cubic and hexagonal diamond structures, respectively (Brunetta *et al.*, 2013). The monovalent ions incorporated in these materials include Li (Wu, Zhang, *et al.*, 2017; Wu & Pan, 2017), Cu (Parthé *et al.*, 1969) or Ag (Brunetta *et al.*, 2013) and the divalent ions include a number of metals, such as Mg (Liu *et al.*, 2013), Mn (Bernert & Pfitzner, 2005), Fe (Wintenberger, 1979), Co (Bernert and Pfitzner 2006), Zn (Parasyuk *et al.*, 2001), Cd (Rosmus *et al.*, 2014) and Hg (Olekseyuk *et al.*, 2005). The tetravalent ions found in these compounds are usually Si, Ge, or Sn, while the hexavalent atoms (*i.e.*, the divalent anions) can be S (Lekse *et al.*, 2009), Se (Gulay, Romanyuk & Parasyuk, 2002), or Te (Parasyuk *et al.*, 2005). Some specific examples include  $\text{Cu}_2\text{MgGeS}_4$  (Liu *et al.*, 2013) and  $\text{Ag}_2\text{MnSnS}_4$  (Friedrich *et al.*, 2018).

In contrast, considerably fewer compounds of the general formula I<sub>4</sub>–II–IV<sub>2</sub>–VI<sub>7</sub> have been discovered: only seven of these, which crystallize in either space group  $C2$  or  $Cc$  with structures derived from cubic or hexagonal diamond, respectively, have been published to date:  $\text{Li}_4\text{MnGe}_2\text{S}_7$  ( $Cc$ ) (Kaib *et al.*, 2013),  $\text{Li}_4\text{MnSn}_2\text{Se}_7$  ( $Cc$ ) (Kaib *et al.*, 2013),  $\text{Li}_4\text{HgGe}_2\text{S}_7$  ( $Cc$ ) (Wu, Yang, Pan 2017),  $\text{Ag}_4\text{HgGe}_2\text{S}_7$  ( $Cc$ ) (Gulay, Olekseyuk & Parasyuk 2002),  $\text{Ag}_4\text{CdGe}_2\text{S}_7$  ( $Cc$ ) (Gulay, Olekseyuk & Parasyuk 2002),  $\text{Cu}_4\text{NiSi}_2\text{S}_7$  ( $C2$ ) (Schäfer *et al.*, 1980), and  $\text{Cu}_4\text{NiGe}_2\text{S}_7$  ( $C2$ ) (Schäfer *et al.*, 1980).

### 4. X-ray powder diffraction and thermal analysis

The calculated and observed X-ray powder diffraction patterns match well (Fig. 4), indicating that the title compounds are the major phases of the respective reactions. An optimization of the synthetic protocol is needed to isolate the desired phases in phase-pure form.

Differential thermal analysis (DTA) reveals that  $\text{Cu}_4\text{FeGe}_2\text{S}_7$  and  $\text{Cu}_4\text{CoGe}_2\text{S}_7$  show relatively high thermal stability and melting and recrystallization events with appropriate hysteresis around 1000°C (Fig. 5). Multiple heating–cooling cycles for each sample were consistent, suggesting that the thermal events are reversible. X-ray powder diffraction of the DTA residues indicated that the samples were not changed by the thermal analyses, implying that they melt congruently. DTA also suggests that neither compound is a single phase, as

**Figure 5**

Differential thermal analysis diagrams obtained for the title compounds showing the melting and recrystallization events.

there are some small shoulders on the peaks indicative of the thermal events.

## 5. Materials and methods

All powdered elements were acquired from commercial suppliers and used as obtained with the exception of germanium metal, which was purchased as chunks and ground to a fine powder using a Diamonite™ mortar and pestle prior to use. Powder X-ray diffraction data were recorded from 10–100° 2θ using a PANalytical X'Pert Pro MPD powder X-ray diffractometer operating with Cu  $K\alpha$  radiation ( $\lambda = 1.541871$  Å), a tube power of 45 kV and 40 mA and a step size of 0.017°. DTA data were obtained using a Shimadzu DTA50 thermal analyzer. Each sample was vacuum-sealed in a fused-silica ampoule, placed alongside an ampoule containing an Al<sub>2</sub>O<sub>3</sub> reference of comparable mass, heated from room temperature to 1050°C at a rate of 10°C min<sup>-1</sup> and subsequently cooled to room temperature at the same rate. A second heating–cooling cycle was conducted in order to determine the reproducibility of the thermal events.

## 6. Synthesis and crystallization

Cu<sub>4</sub>FeGe<sub>2</sub>S<sub>7</sub> and Cu<sub>4</sub>CoGe<sub>2</sub>S<sub>7</sub> were synthesized by combining stoichiometric amounts of Cu (99.999%), Fe (99.99%) or Co (99.99%), Ge (99.999%) and S (99.5%, sublimed) powders. The powders were mixed and placed into 12 mm o.d. fused-

silica tubes that were subsequently attached to a vacuum line, evacuated and flame sealed. The reaction vessels were placed upright into ceramic containers inside programmable furnaces, where they were heated to 1000°C in 24 h, held there for 48 h, cooled to 900°C over the course of 50 h, and held there for 96 h, before being allowed to cool to room temperature over a 24 h period. Subsequently, the reaction vessels were cut open and the contents were examined under a light microscope. The products consisted of loose silvery gray microcrystalline powders from which small single crystals were selected for single-crystal X-ray diffraction.

## 7. Refinement

Crystal data, data collection parameters, and structure refinement details are summarized in Table 3. Extinction parameters were refined for each compound. After the final refinement, the Flack parameter for both structures refined to 0.06 (3), indicating that the absolute structure is correct. In Cu<sub>4</sub>FeGe<sub>2</sub>S<sub>7</sub>, the largest difference peak is located 1.15 Å from Cu2 while the deepest difference hole is 1.50 Å from S3. For Cu<sub>4</sub>CoGe<sub>2</sub>S<sub>7</sub>, the largest difference peak is 0.67 Å from Co while the deepest difference hole is 0.83 Å from Ge.

## Acknowledgements

## Syntheses and crystal structures of the quaternary thiogermanates Cu<sub>4</sub>FeGe<sub>2</sub>S<sub>7</sub> and Cu<sub>4</sub>CoGe<sub>2</sub>S<sub>7</sub>

Andrew J. Craig, Stanislav S. Stoyko, Allyson Bonnoni and Jennifer A. Aitken

### Computing details

For both structures, data collection: SMART (Bruker, 1998); cell refinement: SAINT (Bruker, 1998); data reduction: SAINT (Bruker, 1998); program(s) used to solve structure: SHELXS97 (Sheldrick, 2008); program(s) used to refine structure: SHELXL2018/3 (Sheldrick, 2015); molecular graphics: CrystalMaker (Palmer, 2014); software used to prepare material for publication: SHELXL2018/3 (Sheldrick, 2015).

### Tetracopper iron digermanium heptasulfide (I)

#### Crystal data

Cu <sub>4</sub> FeGe <sub>2</sub> S <sub>7</sub>	<i>F</i> (000) = 636
<i>M<sub>r</sub></i> = 679.61	<i>D<sub>x</sub></i> = 4.350 Mg m <sup>-3</sup>
Monoclinic, <i>C</i> 2	Mo <i>Kα</i> radiation, $\lambda$ = 0.71073 Å
<i>a</i> = 11.7405 (6) Å	Cell parameters from 4891 reflections
<i>b</i> = 5.3589 (2) Å	$\theta$ = 4.2–31.4°
<i>c</i> = 8.3420 (4) Å	$\mu$ = 16.46 mm <sup>-1</sup>
$\beta$ = 98.661 (3)°	<i>T</i> = 296 K
<i>V</i> = 518.86 (4) Å <sup>3</sup>	Irregular, grey
<i>Z</i> = 2	0.08 × 0.08 × 0.03 mm

#### Data collection

Bruker SMART APEXII	1187 independent reflections
diffractometer	994 reflections with $I > 2\sigma(I)$
$\varphi$ and $\omega$ Scans scans	$R_{\text{int}}$ = 0.021
Absorption correction: multi-scan	$\theta_{\text{max}} = 27.5^\circ$ , $\theta_{\text{min}} = 2.5^\circ$
(SADABS; Sheldrick, 2002)	$h = -15 \rightarrow 15$
$T_{\text{min}} = 0.246$ , $T_{\text{max}} = 0.435$	$k = -6 \rightarrow 6$
2258 measured reflections	$l = -10 \rightarrow 10$

#### Refinement

Refinement on $F^2$	$w = 1/[\sigma^2(F_o^2) + (0.0315P)^2]$
Least-squares matrix: full	where $P = (F_o^2 + 2F_c^2)/3$
$R[F^2 > 2\sigma(F^2)] = 0.034$	$(\Delta/\sigma)_{\text{max}} < 0.001$
$wR(F^2) = 0.094$	$\Delta\rho_{\text{max}} = 0.75$ e Å <sup>-3</sup>
$S = 1.06$	$\Delta\rho_{\text{min}} = -0.89$ e Å <sup>-3</sup>
1187 reflections	Extinction correction: SHELXL-2018/3
67 parameters	(Sheldrick 2018), $F_c^* = kFc[1 + 0.001xFc^2\lambda^3/\sin(2\theta)]^{-1/4}$
1 restraint	Extinction coefficient: 0.0123 (9)
Primary atom site location: structure-invariant direct methods	Absolute structure: Flack (1983)
	Absolute structure parameter: 0.06 (3)

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** Refined as a two-component inversion twin
