Crystals of 1,10-phenanthroline pentafluoridooxidotungstate(VI), (1,10-phen-H)[ $\text{WOF}_5$ ] (1,10-phen = 1,10-phenanthroline,  $\text{C}_{12}\text{H}_8\text{N}_2$ ), were obtained upon hydrolysis of  $\text{WF}_6(1,10\text{-phen})$  in  $\text{CH}_3\text{CN}$  at 193 K. The (1,10-phen-H)[ $\text{WOF}_5$ ] salt contains a rare example of a  $[\text{WOF}_5]^-$  anion in which the oxygen and fluorine atoms are ordered. This ordering was verified by bond-valence determinations and structural comparisons with  $[\text{Xe}_2\text{F}_{11}][\text{WOF}_5]$  and Lewis acid-base adducts of  $\text{WOF}_4$  with main-group donor ligands. The crystal packing is controlled by  $\text{N}-\text{H}\cdots\text{F}$  hydrogen bonding that is directed exclusively to the axial F atom as a result of its increased basicity caused by the *trans* influence of the oxido ligand.

## 1. Chemical context

The crystal structure of tetrameric, fluorine-bridged  $\text{WOF}_4$  (Edwards & Jones, 1968), as well as those of various fluorido-oxidotungstates(VI) of the form  $[\text{WO}_n\text{F}_{6-n}]^{n-}$  ( $n = 1-3$ ), are characterized by extensive disorder between the oxido and fluorido ligands (Voit *et al.*, 2006). Such disorder complications originally led to the incorrect assumption that  $\text{WOF}_4$  existed as an oxygen-bridged species. This was later disproved by vibrational spectroscopic studies of  $\text{WOF}_4$  that revealed exclusively terminal  $\text{W}=\text{O}$  bonds (Bennett *et al.*, 1972; Asprey *et al.*, 1972). In  $[\text{WO}_n\text{F}_{6-n}]^{n-}$  anions, the nature of the O/F disorder can be controlled by the properties of the counterions. For example,  $\text{Na}[\text{WO}_2\text{F}_4]$  is ordered (Vlasse *et al.*, 1982; Chaminade *et al.*, 1986), whereas  $\text{Rb}[\text{WO}_2\text{F}_4]$  (Udovenko & Laptash, 2008a) and  $\text{Cs}[\text{WO}_2\text{F}_4]$  (Srivastava *et al.*, 1992) are statically disordered, and  $[\text{NH}_4]_2[\text{WO}_2\text{F}_4]$  exhibits simultaneous static and dynamic disorder, both of which are quenched below 201 K to reveal an ordered structure (Udovenko & Laptash, 2008b). In addition, the double salt,  $[\text{HNC}_6\text{H}_6\text{OH}]_2[\text{Cu}(\text{NC}_5\text{H}_5)_4][\text{WO}_2\text{F}_4]_2$ , exhibits ordered  $[\text{WO}_2\text{F}_4]^{2-}$  anions at 153 K as a result of  $\text{H}\cdots\text{F}$  and  $\text{Cu}\cdots\text{O}$  secondary-bonding interactions (Welk *et al.*, 2001). An ordered  $[\text{WO}_3\text{F}_3]^{3-}$  fragment was identified within  $\text{Pb}_5\text{W}_3\text{O}_9\text{F}_{10}$  (Abrahams *et al.*, 1987) and, despite extensive dynamic disorder within  $[\text{NH}_4]_3[\text{WO}_3\text{F}_3]$  (Voit *et al.*, 2006), the stereochemistry could be resolved from the observed displacement of the tungsten atoms from their octahedral symmetry centres (Udovenko & Laptash, 2008a). In all cases, mutual *cis* arrangements of the oxido ligands are preferred (*i.e.*, *cis*- $[\text{WO}_2\text{F}_4]^{2-}$  and *fac*- $[\text{WO}_3\text{F}_3]^{3-}$ ). A *trans* influence from the oxido ligands results in increased electron density on

the effected fluorido ligands, and it is these fluorido ligands that participate in fluorine bridging within multinuclear systems, such as in  $\text{WOF}_4$  and in various  $[\text{W}_2\text{O}_2\text{F}_9]^-$  salts with different counterions  $\{[\text{H}_3\text{O}]^+(\text{Hoskins et al., 1987}); [\text{WF}_4(2,2'\text{-bipy})_2]^{2+}(\text{Arnaudet et al., 1992}); [\text{Os}_3(\text{CO})_{12}\text{H}]^+(\text{Crossman et al., 1996}); [\text{XeF}_5]^+(\text{Bortolus et al., 2020}); \text{Li}-\text{Cs}^+(\text{Stene et al., 2020})\}$ , and in  $[\text{W}_2\text{O}_4\text{F}_6]^{2-}$  (Wollert et al., 1991).

Crystallographically characterized  $[\text{WOF}_5]^-$  salts with a range of counterions  $\{[\text{As}(\text{C}_6\text{H}_5)_4]^+(\text{Massa et al., 1982}); [\text{Cs}(15\text{-crown-5})_2]^+(\text{Nuszhar et al., 1992}); \text{Ag}^{2+}(\text{Mazej et al., 2017}); [\text{WF}_4(1,2\text{-}\{\text{P}(\text{CH}_3)_2\}_2\text{C}_6\text{H}_4)]^{2+}(\text{Levason et al., 2018})\}$  have exhibited some degree of O/F disorder in the anion, obfuscating the  $\text{W}=\text{O}$  and  $\text{W}-\text{F}$  bond lengths. Recently, however,  $[\text{Xe}_2\text{F}_{11}][\text{WOF}_5]$  and  $[\text{XeF}_5][\text{WOF}_5]\cdot\text{XeOF}_4$  were reported to contain  $[\text{WOF}_5]^-$  anions that are ordered as a consequence of multiple  $\text{Xe}\cdots\text{F}-\text{W}$  interactions (Bortolus et al., 2020). Herein, we report a new ordered  $[\text{WOF}_5]^-$  salt in the form of  $(1,10\text{-phen-H})[\text{WOF}_5]$  (Fig. 1), obtained during an attempted crystallization of  $\text{WF}_6(1,10\text{-phen})$  (Turnbull et al., 2019a).

## 2. Structural commentary

The  $\text{W}=\text{O}$  bond length in  $(1,10\text{-phen-H})[\text{WOF}_5]$  [1.698 (2) Å] is indistinguishable from those in  $[\text{Xe}_2\text{F}_{11}][\text{WOF}_5]$  [1.698 (3) Å; Bortolus et al., 2020],  $\text{WOF}_4\{\text{OP}(\text{C}_6\text{H}_5)_3\}$  [1.682 (5) Å; Levason et al., 2016] and  $\text{WOF}_4(\text{NC}_5\text{H}_5)$  [1.690 (3) Å; Turnbull et al., 2019b]. The  $\text{W}-\text{F}_{\text{eq}}$  bond lengths

**Figure 1**  
Displacement ellipsoid plot (50% probability level) of  $(1,10\text{-phen-H})[\text{WOF}_5]$ .

**Table 1**

Bond valences and sums of the  $[\text{WOF}_5]^-$  anion in  $(1,10\text{-phen-H})[\text{WOF}_5]$ .

	$\nu_i^a$		$V^b$
		W	5.98
W=O	1.81	O	1.88
W-F1	0.62	F1	0.81
W-F2	0.89	F2	0.95
W-F3	0.88	F3	0.94
W-F4	0.90	F4	0.97
W-F5	0.87	F5	0.95

Notes: (a) Defined as  $\nu_i = \exp [R_o - R/b]$ , where  $R$  is the observed bond length (in Å) and  $R_o$  and  $b$  are empirical parameters (Brown & Altermatt, 1985; Brese & O'Keeffe, 1991; Brown, 2002; Adams et al., 2004). (b) Defined as  $V = \Sigma(\nu_i)$ . Only secondary contacts within the sum of the van der Waals radii (Bondi, 1964) were considered.

[1.8677 (15)–1.8809 (15) Å] are also insignificantly different from those in  $\text{WOF}_4\{\text{OP}(\text{C}_6\text{H}_5)_3\}$  [1.857 (3)–1.871 (3) Å; Levason et al., 2016] and  $\text{WOF}_4(\text{NC}_5\text{H}_5)$  [1.859 (3)–1.868 (3) Å; Turnbull et al., 2019b]. The  $\text{W}-\text{F}_{\text{eq}}$  bonds in  $[\text{Xe}_2\text{F}_{11}][\text{WOF}_5]$  (Bortolus et al., 2020) are also of similar lengths to those in the title compound, although one terminal  $\text{W}-\text{F}_{\text{eq}}$  bond [1.848 (2) Å] is significantly shorter in the  $[\text{Xe}_2\text{F}_{11}]^+$  salt, and one bridging bond significantly longer [1.900 (2) Å].

The  $\text{W}-\text{F}_{\text{ax}}$  bond length of  $(1,10\text{-phen-H})[\text{WOF}_5]$  [2.0048 (15) Å] is slightly shorter than those in  $[\text{Xe}_2\text{F}_{11}][\text{WOF}_5]$  [2.047 (2) Å; Bortolus et al., 2020] and  $[\text{C}_5\text{H}_5\text{NH}][\text{W}(\text{NC}_6\text{F}_5)\text{F}_5]$  [2.0212 (13) Å; Turnbull et al., 2017]. In the latter compound, the  $\text{N1}-\text{H1}\cdots\text{F1}$  interaction resulted in the significant elongation of the  $\text{W}-\text{F}_{\text{ax}}$  bond with respect to that observed in  $[\text{N}(\text{CH}_3)_4][\text{W}(\text{NC}_6\text{F}_5)\text{F}_5]$  [1.973 (3) Å; Turnbull et al., 2017]. Gas-phase geometry optimizations of the  $[\text{Xe}_2\text{F}_{11}][\text{WOF}_5]$  ion pair and free  $[\text{WOF}_5]^-$  corroborated a significant elongation of the  $\text{W}-\text{F}_{\text{ax}}$  bond in the former anion compared to the latter (2.148 vs 1.972 Å, respectively) arising from cation–anion interactions (Bortolus et al., 2020).

The individual bond valences of the  $[\text{WOF}_5]^-$  anion in  $(1,10\text{-phen-H})[\text{WOF}_5]$  (Table 1) reveal that the  $\text{W}=\text{O}$  bond ( $\nu = 1.81$ ) is approximately double the strength of the  $\text{W}-\text{F}_{\text{eq}}$  bonds ( $\nu = 0.87\text{--}0.90$ ), indicating complete O/F ordering; in a disordered anion, the  $\text{W}=\text{O}$  bond valence is artificially decreased due to averaging with the  $\text{W}-\text{F}$  single bonds. The F1 atom possesses a valence sum significantly less than unity ( $V = 0.81$ ) because of the *trans* influence of the oxido ligand and  $\text{N1}-\text{H1}\cdots\text{F1}$  hydrogen-bonding interaction substantially polarizing that bond.

## 3. Supramolecular features

Besides the  $\text{N1}-\text{H1}\cdots\text{F1}$  hydrogen-bonding interactions, there also exist weak intermolecular  $\text{C5}\cdots\text{O}$  [3.163 (3) Å] and  $\text{C3}\cdots\text{C10}$  [3.204 (4) Å] interactions that result in the formation of columns of cations and anions running parallel to the *a* axis (Fig. 2) in the packed crystal. The crystal packing, however, appears to be dominated by the  $\text{N1}-\text{H1}\cdots\text{F1}$  hydrogen bonds (Table 2) and other intermolecular interactions, such as  $\pi$ – $\pi$  stacking interactions between cations, are absent.

**Table 2**  
Hydrogen-bond geometry (Å, °).

$D-H\cdots A$	$D-H$	$H\cdots A$	$D\cdots A$	$D-H\cdots A$
N1–H1 $\cdots$ F1	0.89 (3)	1.88 (3)	2.704 (3)	154 (3)

#### 4. Synthesis and crystallization

In the dry box, a 1/4"-o.d. FEP reactor, equipped with a 316-stainless-steel valve and pre-passivated with F<sub>2</sub> (100%, Linde Gas), was charged with WF<sub>6</sub>(1,10-phen) (*ca* 0.01 g), prepared as described previously (Turnbull *et al.*, 2019a). Acetonitrile (*ca* 0.1 mL), dried as previously described (Winfield, 1984), was distilled into the reactor through a glass vacuum line equipped with grease-free PTFE stopcocks (J. Young). The reactor was heated to 353 K in a hot-water bath and allowed to cool to ambient temperature over 16 h. The reactor was then

Computer programs: *CrysAlis PRO* (Rigaku OD, 2015), *SHELXT* (Sheldrick, 2015a), *SHELXL* (Sheldrick, 2015b), *XP* (Sheldrick, 2008), *OLEX2* (Dolomanov *et al.*, 2009) and *publCIF* (Westrip, 2010).

cooled rapidly to 233 K and the solvent was removed under dynamic vacuum at that temperature, resulting in the formation of colourless needles of (1,10-phen-H)[WOF<sub>5</sub>], together with an off-white microcrystalline material that was not further characterized, but is presumed to contain WF<sub>6</sub>(1,10-phen) and (1,10-phen-H)[WOF<sub>5</sub>].

The reactor was cut open and the crystals transferred onto an aluminium trough cooled to 193 K under a constant stream of liquid-N<sub>2</sub>-cooled, dry N<sub>2</sub>. The selected crystal was affixed to a Nylon cryo-loop submerged in perfluorinated polyether oil (Fomblin Z-25) and quickly transferred to the goniometer to minimize exposure to air.

#### 5. Refinement details

Crystallographic data collection and refinement parameters are summarized in Table 3. All the hydrogen atoms were located in difference Fourier maps and were refined using a riding model, with the exception of H1, the position of which was refined freely (Table 2).

Hydrogen site location: mixed

H atoms treated by a mixture of independent  
and constrained refinement $w = 1/[\sigma^2(F_o^2) + (0.0179P)^2 + 0.7231P]$ where  $P = (F_o^2 + 2F_c^2)/3$  $(\Delta/\sigma)_{\max} = 0.002$  $\Delta\rho_{\max} = 0.97 \text{ e } \text{\AA}^{-3}$  $\Delta\rho_{\min} = -0.83 \text{ e } \text{\AA}^{-3}$ *Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
