The title compound,  $C_{15}H_{15}Br_2NO_2$ , crystallizes with two molecules in the asymmetric unit of the unit cell. In both molecules, the tetrahydrofuran rings adopt an envelope conformation with the O atom as the flap and the pyrrolidine rings adopt an envelope conformation. In the crystal, molecules are linked by weak C—H···O hydrogen bonds, forming sheets lying parallel to the (002) plane. These sheets are connected only by weak van der Waals interactions. The most important contributions to the surface contacts are from H···H (44.6%), Br···H/H···Br (24.1%), O···H/H···O (13.5%) and C···H/H···C (11.2%) interactions, as concluded from a Hirshfeld surface analysis.

## 1. Chemical context

Halogenation is a chemical reaction that involves the introduction of one or more halogen atoms to an organic molecule. The pathway and stereochemistry of halogenation reactions is dependent on the configuration of the starting olefine and the halogenating agent. The role/behavior of the attached halogen atom in olefines can be classified into the following types: (1) as an electron-withdrawing substituent, (2) as a halogen-bond donor center, and (3) as a non-covalent bond acceptor site. Thus, not only hydrogen bonding (Gurbanov *et al.*, 2018; Kopylovich *et al.*, 2011) or other types of non-covalent interactions (Afkhami *et al.*, 2017; Asadov *et al.*, 2016; Ma *et al.*, 2017a,b; 2020; Mahmudov *et al.*, 2010; 2019; 2020, but also halogen bonding can be used in the design of olefines. In this work, we proposed and tested inexpensive and readily available bis[*N,N*-dimethylacetamide] hydrogen dibromobromate  $[(Me_2NCOMe)_2H]Br_3$  as a bromine initiator and a source of a positively charged bromine ion (Rodygin *et al.*, 1992; Prokop'eva *et al.*, 1994; Prokop'eva, 2008). The choice of  $[(Me_2NCOMe)_2H]Br_3$ , obtained by one-pot synthesis from *N,N*-dimethylacetamide, hydrobromic acid and bromine, is down to the simplicity of the synthesis and isolation, and the unambiguous direction of the bromination process. In addition,  $[(Me_2NCOMe)_2H]Br_3$  is an excellent reagent for functionalization of phenols and anilines (Rodygin *et al.*, 1992; Mikhailov *et al.*, 1993), and is also used in the synthesis of mono-bromo-substituted ketones (Rodygin *et al.*, 1994;

Burakov *et al.*, 2001) and for the bromination of various alkenes and alkynes (Rodygin *et al.*, 1994; Zaytsev *et al.*, 2017). The present work is aimed at accumulating experimental data and establishing the rules of the halogenation in bridged epoxy-isoindolones (Zubkov *et al.*, 2018; Zaytsev *et al.*, 2020). The reaction of *N*-benzyltetrahydroepoxyisoindolone (**1**) with  $[(\text{Me}_2\text{NCO})_2\text{H}]\text{Br}_3$  in dry chloroform under reflux leads to the corresponding 2-benzyl-4,5-dibromohexahydro-3a,6-epoxyisoindol-1(4*H*)-one (**2**) (Fig. 1).

## 2. Structural commentary

The asymmetric unit of the title compound (Fig. 2) contains two molecules of similar shape, hereafter referred to as molecules *A* (including atom C1*A*) and *B* (including atom C1*B*). The conformational differences between molecules *A* and *B* are highlighted in an overlay diagram shown in Fig. 3. The r.m.s. deviation of the overlay between the molecules *A* and *B* is 0.114 Å.

In both molecules *A* and *B*, the pyrrolidine rings (*N*1*A/C5A–C8A* and *N*1*B/C5B–C8B*), tetrahydrofuran rings (*O*1*A/C1A–C3A/C6A*, *O*1*A/C3A–C6A* and *O*1*B/C1B–C3B/C6B*, *O*1*B/C3B–C6B*) and six-membered rings (*C*1*A–C6A* and *C*1*B–C6B*), which generate epoxyisoindole moieties (*O*1*A/N1A/C1A–C8A* and *O*1*B/N1B/C1B–C8B*), are puckered. In molecule *A*, both tetrahydrofuran rings adopt an envelope conformation with puckering parameters (Cremer & Pople, 1975)  $Q(2) = 0.575(3)$  Å,  $\varphi(2) = 182.2(4)^\circ$  for (*O*1*A/C1A–C3A/C6A*) and  $Q(2) = 0.558(4)$  Å,  $\varphi(2) = 3.8(4)^\circ$  for (*O*1*A/C3A–C6A*), respectively. In molecule *B*, both tetrahydrofuran rings also adopt an envelope conformation with puckering parameters  $Q(2) = 0.575(4)$  Å,  $\varphi(2) = 182.7(4)^\circ$  for (*O*1*B/C1B–C3B/C6B*) and  $Q(2) = 0.556(4)$  Å,  $\varphi(2) = 3.7(4)^\circ$  for (*O*1*B/C3B–C6B*).

The five-membered pyrrolidine rings also exhibit an envelope conformation, with a maximum deviation from the mean plane of 0.155 (3) Å at C6A [puckering parameters  $Q(2) = 0.248$  (4) Å,  $\varphi(2) = 77.7$  (8)°] for molecule A and 0.153 (3) Å at C6B [puckering parameters  $Q(2) = 0.243$  (4) Å,  $\varphi(2) = 75.0$  (9)°] for molecule B. In both molecules, the six-membered ring has a boat conformation [ $Q_T = 0.921$  (4) Å,  $\theta = 91.8$  (2)°,  $\varphi = 119.3$  (2)° for molecule A;  $Q_T = 0.919$  (4) Å,  $\theta = 91.9$  (2)°,  $\varphi = 119.6$  (3)° for molecule B].

### 3. Supramolecular features

In the crystal, molecules are linked by weak C—H···O hydrogen bonds, forming sheets lying parallel to the (002) plane (Table 1, Figs. 4 and 5). These sheets are connected only by weak van der Waals interactions.

#### 4. Hirshfeld surface analysis

The intermolecular interactions (Table 2) were investigated quantitatively and visualized with *Crystal Explorer 3.1* (Wolff *et al.*, 2012; Spackman *et al.*, 2009). The Hirshfeld surface plotted over  $d_{\text{norm}}$  in the range  $-0.0815$  to  $0.9926$  a.u. is shown in Fig. 6. The red spots on the Hirshfeld surface represent  $\text{C}-\text{H}\cdots\text{O}$  contacts. Fig. 7 shows the full two-dimensional fingerprint plot and those delineated into the major contacts: the  $\text{H}\cdots\text{H}$  (44.6%) interactions are the major factor in the crystal packing with  $\text{Br}\cdots\text{H}/\text{H}\cdots\text{Br}$  (24.1%),  $\text{O}\cdots\text{H}/\text{H}\cdots\text{O}$  (13.5%) and  $\text{C}\cdots\text{H}/\text{H}\cdots\text{C}$  (11.2%) interactions representing the next highest contributions. The percentage contributions of other weak interactions are listed in Table 3.

In the crystal of AGONUH, the molecules are linked by C—H···O hydrogen bonds into zigzag chains running along the *b*-axis direction. In TIJMIK, two types of C—H···O hydrogen bonds generate  $R_2^2(20)$  and  $R_4^4(26)$  rings, with adjacent rings running parallel to *ac* plane. In addition C—H···O hydrogen bonds form a *C*(6) chain, linking the molecules in the *b*-axis direction. In YAXCIL and UPAQEI, molecules are also linked by C—H···O hydrogen bonds. In the crystal of ERIVIL, weak intermolecular C—H···O hydrogen bonds link the molecules into  $R_2^2(8)$  and  $R_2^2(14)$  rings along the *b*-axis direction. In MIGTIG, the molecules are linked only by weak van der Waals interactions.

## 6. Synthesis and crystallization

A solution of isoindolone **1** (4 mmol) and the brominating agent (4 mmol) in dry chloroform (15 mL) was heated under reflux for 18 h (TLC control, EtOAc–hexane, 1:1). The reaction mixture was poured into H<sub>2</sub>O (50 mL) and extracted with CHCl<sub>3</sub> (3 × 20 mL). The combined organic fractions were dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>, the solvent was evaporated under reduced pressure, and the residue was purified by column chromatography (SiO<sub>2</sub>, 15 × 1.8 cm, hexane/EtOAc,

10:1). Colourless hexagonal prisms. Yield 0.46 g (29%), m.p. > 428 K (decomposition).

## 7. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4. C-bound H atoms were positioned geometrically, with C—H = 0.93 Å (for aromatic H atoms), C—H = 0.98 Å (for methine H atoms), 0.97 Å (for methylene H atoms) and 0.96 Å (for methyl H atoms), and constrained to ride on their parent atoms, with  $U_{\text{iso}}(\text{H})$  = 1.2 $U_{\text{eq}}(\text{C})$  or 1.5 $U_{\text{eq}}(\text{C-methyl})$ . Ten reflections (101), (101), (111), (002), (111), (110), (200), (103), (202) and (112) were obscured by the beam stop and omitted during the final refinement cycle.

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
