Crystal structure of a methanol solvate of a macrocycle bearing two flexible side-arms

Felix Amrhein, Anke Schwarzer and Monika Mazik*Technische Universität Bergakademie Freiberg, Leipziger Str. 29, D-09596 Freiberg/Sachsen, Germany. *Correspondence
e-mail: monika.mazik@chemie.tu-freiberg.de

Di-*tert*-butyl *N,N'*-{[13,15,28,30,31,33-hexaethyl-3,10,18,25,32,34-hexaazapenta-cyclo[25.3.1.1^{5,8}.1^{12,16}.1^{20,23}]tetraconta-1(31),3,5,7,9,12(33),13,15,18,20,22,24,-27,29-tetradecaene-14,29-diy]bis(methylene)}dicarbamate methanol solvate, C₅₂H₇₂N₈O₄·2CH₃OH, was found to crystallize in the space group *P*2₁/c with one half of the macrocycle (host) and one molecule of solvent (guest) in the asymmetric unit of the cell, *i.e.* the host molecule is located on a crystallographic symmetry center. Within the 1:2 host–guest complex, the solvent molecules are accommodated in the host cavity and held in their positions by O—H···N and N—H···O bonds, thus forming ring synthons of graph set R₂²(7). The connection of the 1:2 host-guest complexes is accomplished by C—H···O, C—H···N and C—H···π interactions, which create a three-dimensional supramolecular network.

1. Chemical context

Representatives of compounds consisting of a macrocyclic building block and two flexible side-arms have been shown to be able to act as powerful carbohydrate-binding agents (artificial carbohydrate receptors). Depending on the nature of their building blocks, various receptors with different binding properties could be developed (Lippe & Mazik, 2013, 2015; Amrhein *et al.*, 2016.). The design of such a receptor architecture was inspired by the results of our crystallographic studies, including the analyses of the binding motifs in complexes formed between acyclic receptors and monosaccharides, reported by us some time ago (Mazik *et al.*, 2005). At this point it should be noted that, in contrast to numerous known crystal structures of protein–carbohydrate complexes, there are only individual literature reports on the crystal structures of complexes formed between artificial receptors and sugars (for a recent report on such crystalline complexes, see Köhler *et al.*, 2020). The syntheses of the above-mentioned receptors, combining a macrocyclic building block and flexible side-arms, involve the preparation of macrocyclic precursors containing four imine functionalities. The crystal structure of one of such macrocyclic precursors is described in this work. This macrocycle bears two identical side-arms, containing the *tert*-butyloxycarbonyl group (BOC group), and is composed of two triethylbenzene units connected by two bridges, each bearing one pyrrole moiety and two imine functionalities.

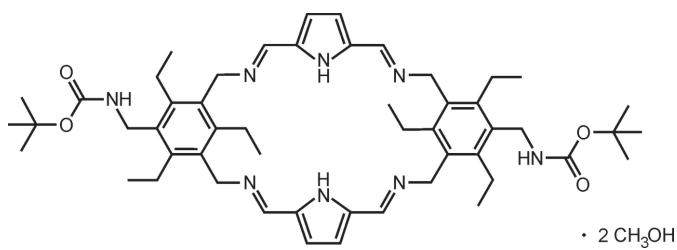

2. Structural commentary

The title compound was found to crystallize as a methanol solvate of the space group *P*2₁/c with the asymmetric unit of

OPEN ACCESS

the cell containing one half of the macrocycle and one solvent molecule (the structure of the 1:2 host-guest complex is shown in Fig. 1), *i.e.* the host molecule is located on a symmetry center. The bond lengths and angles confirm the expected structure and thus the presence of imino groups within the cyclic backbone [$\text{N}2-\text{C}16 = 1.273$ (2); $\text{N}2-\text{C}15 = 1.478$ (2); $\text{N}4-\text{C}24 = 1.274$ (2); $\text{N}4-\text{C}23 = 1.463$ (2) Å]. The substituents attached to the benzene ring adopt a fully alternating arrangement above and below the ring plane, *i.e.* the three ethyl groups all point in the opposite direction with regard to the pyrrole-based bridges connecting the two triethylbenzene units. The dihedral angle between the least-squares planes of the pyrrole and benzene rings is 76.0 (1)°, which corresponds with the torsion angles of 178.58 (12) and −131.22 (12)° for the atomic sequences $\text{C}16-\text{N}2-\text{C}15-\text{C}3$ and $\text{C}24-\text{N}4-\text{C}23-\text{C}5$, respectively. In the case of the side-arm bearing the BOC group the torsion angle along the atomic sequence $\text{C}8-\text{N}1-\text{C}7-\text{C}1$ amounts to 126.91 (14)°, whereas the torsion angles for the atom sequences $\text{C}8-\text{O}1-\text{C}9-\text{C}10$, $\text{C}8-\text{O}1-\text{C}9-\text{C}11$ and $\text{C}8-\text{O}1-\text{C}9-\text{C}12$ are −67.15 (15), 175.36 (12) and 57.39 (16)°.

3. Supramolecular features

Within the 1:2 host-guest complex, each of the methanol molecules interacts with the host by a $\text{O}-\text{H}\cdots\text{N}_{\text{imine}}$ [$d(\text{H}\cdots\text{N}) = 1.82$ (3) Å] and an $\text{N}_{\text{pyrrole}}-\text{H}\cdots\text{O}$ hydrogen bond [$d(\text{H}\cdots\text{O}) = 2.10$ (2) Å] that generate a cyclic synthon with a $R_2^2(7)$ motif according to Etter's definition (Etter, 1990; Bernstein *et al.*, 1995). Thus, the hydroxy group of each of the

Symmetry codes: (i) $-x, -y + 1, -z + 1$; (ii) $x + 1, -y + \frac{1}{2}, z + \frac{1}{2}$; (iii) $-x + 1, -y + 1, -z$; (iv) $-x, -y + 1, -z$; (v) $x - 1, y, z$; (vi) $x, -y + \frac{1}{2}, z - \frac{1}{2}$.

methanol molecules participates in cooperative hydrogen bonds. The host–guest complexes are connected primarily by interactions involving the carbonyl oxygen atoms. Here, $\text{O}2$ acts as a bifurcated acceptor for the formation of $\text{C}-\text{H}\cdots\text{O}=\text{C}$ bonds [$d(\text{H}\cdots\text{O}) = 2.49, 2.52$ Å], in which the imine atom $\text{H}24$ (see Figs. 2 and 3) and the pyrrole atom $\text{H}18$ of different molecules are included. The second oxygen atom of the BOC group provides a weak $\text{C}-\text{H}\cdots\text{O}$ bond involving the *tert*-butyl group of the neighboring molecule, which further participates in intermolecular $\text{C}-\text{H}\cdots\pi$ interactions with the pyrrole unit of an adjacent host molecule, as shown in Fig. 3 [$d(\text{H}\cdots\text{Cg}) = 3.00$ Å]. In addition, the imine atom $\text{H}16$ contributes to formation of a $\text{C}-\text{H}\cdots\pi$ contact (see Fig. 2) with the pyrrole ring [$d(\text{H}\cdots\text{Cg}) = 2.88$ Å]. The sum of these interactions creates a three-dimensional supramolecular architecture. Numerical details are given in Table 1.

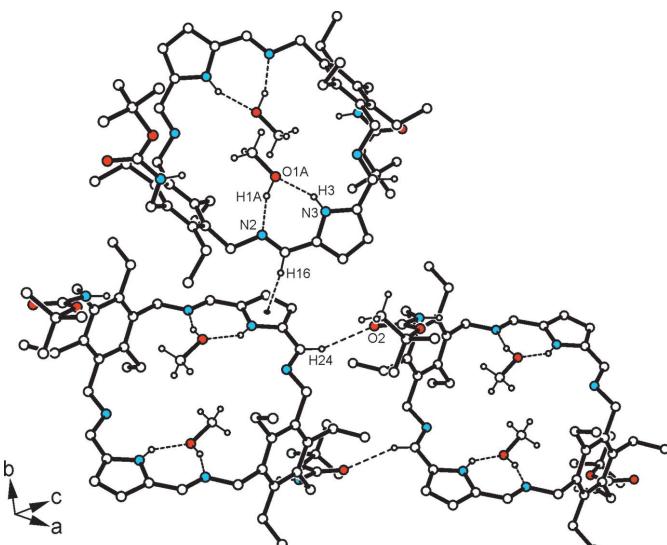

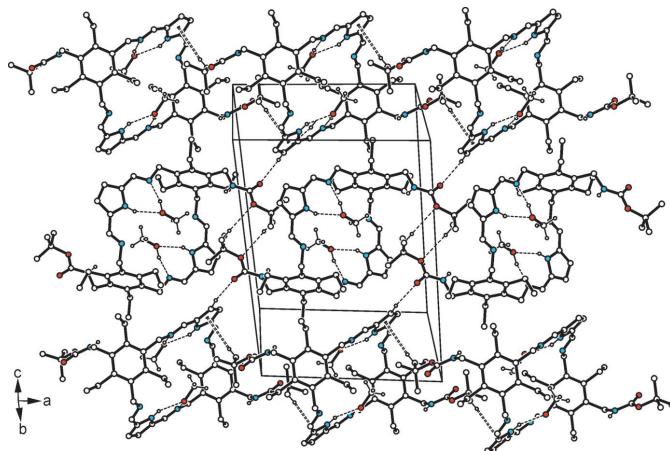

Figure 2

Part of the crystal structure of the 1:2 host-guest complex showing the mode of non-covalent intermolecular bonding. For the sake of clarity, the H atoms of the host molecule not involved in hydrogen-bonding interactions are omitted.

**Figure 3**

Packing diagram of the 1:2 host–guest complex. Hydrogen bonds and C—H···π interactions are represented by dashed lines and dashed double lines, respectively. For the sake of clarity, the H atoms of the host molecule not involved in hydrogen-bonding interactions or C—H···π contacts are omitted.

4. Database survey

A search of the Cambridge Structural Database (CSD, Version 5.41, update November 2019; Groom *et al.* 2016) for macrocyclic compounds containing two 2,4,6-triethylbenzene units and at least two pyrrole-based bridges connecting the two benzene rings gave four hits. They include multi-pyrrolic tripodal cages (ZOMPEZ; Wang *et al.*, 2019), a macrobicyclic cage (PEPGIB; Francesconi *et al.*, 2006), a hexamine macrobicycle with bound sulfate anion (ZOQCAL; Mateus *et al.*, 2015) as well as a macrobicycle with encapsulated phosphate ion (FOMBAN; Oh *et al.*, 2019). All four structures show an alternating orientation of the ring substituents.

5. Synthesis and crystallization

1-{[(1,1-Dimethylethoxy)carbonyl]aminomethyl}-3,5-bis(aminomethyl)-2,4,6-triethylbenzene (Wiskur *et al.*, 2004) (172 mg, 0.50 mmol) was dissolved in dry ethanol (6 ml) and 1*H*-pyrrol-2,5-dicarboxaldehyde (61 mg, 0.50 mmol) was added. After the addition of a catalytic amount of acetic acid, the reaction mixture was stirred for 5 h at 318 K. The precipitated solid was filtered off, washed with small amount of dry ethanol and dried under vacuum. The product was obtained as a white solid (173 mg, 0.20 mmol, 81%). M.p. 533 K (decomp.); ¹H NMR (500 MHz, CDCl₃): δ = 1.17 (*t*, 6H, *J* = 7.5 Hz), 1.21 (*t*, 12H, *J* = 7.5 Hz), 1.38 (*s*, 18H), 2.57 (*q*, 8H, *J* = 7.5 Hz), 3.01–3.09 (*m*, 4H), 4.26 (*d*, 4H, *J* = 4.2 Hz), 4.36 (*s*, 2H), 4.72 (*br*, *s*, 8H), 6.51 (*s*, 4H), 8.22 (*s*, 4H), 9.54 (*s*, 2H) ppm. ¹³C NMR (125 MHz, CDCl₃): δ = 15.01, 16.23, 22.43, 22.45, 28.39, 38.76, 57.97, 79.20, 114.11, 131.51, 132.85, 133.43, 142.74, 144.10, 151.10, 155.52 ppm; HRMS (ESI): C₅₂H₇₂N₈O₄ calculated for [M + H]⁺: 873.57493, found: 873.57663. Crystals suitable for single crystal X-ray diffraction were grown by slow evaporation of the solvent from the methanol solution of compound (I) at room temperature.

Computer programs: APEX2 and SAINT (Bruker, 2007), SIR2014 (Burla *et al.*, 2015), SHELXL2018/3 (Sheldrick, 2015), XP (Sheldrick, 2008), WinGX (Farrugia, 2012), publCIF (Westrip, 2010) and shelXle (Hübschle *et al.*, 2011).

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. The non-hydrogen atoms were refined anisotropically. The NH and OH hydrogens were located in a difference-Fourier map and refined freely. All other hydrogen atoms were positioned geometrically and allowed to ride on their parent atoms: C—H = 0.95 Å for imine and pyrrol H atoms, C—H = 0.99 Å for methylene groups and C—H = 0.98 Å for methyl groups with *U*_{iso}(H) = 1.5*U*_{eq}(C) for methyl groups and *U*_{iso}(H) = 1.2*U*_{eq}(C) for other hydrogen atoms.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Symmetry code: (i) $-x+1, -y+1, -z+1$.

Hydrogen-bond geometry (\AA , $^{\circ}$)

Cg2 represents the centroid of the C17—C20/N3 ring.
