Three cyclopentadienylmolybdenum(II) propionyl complexes featuring triarylphosphine ligands with different *para* substituents, namely, dicarbonyl( $\eta^5$ -cyclopentadienyl)propionyl(triphenylphosphane- $\kappa P$ )molybdenum(II),  $[\text{Mo}(\text{C}_5\text{H}_5)(\text{C}_3\text{H}_5\text{O})(\text{C}_{18}\text{H}_{15}\text{P})(\text{CO})_2]$ , (1), dicarbonyl( $\eta^5$ -cyclopentadienyl)-propionyl[tris(4-fluorophenyl)phosphane- $\kappa P$ ]molybdenum(II),  $[\text{Mo}(\text{C}_5\text{H}_5)(\text{C}_3\text{H}_5\text{O})(\text{C}_{18}\text{H}_{12}\text{F}_3\text{P})(\text{CO})_2]$ , (2), and dicarbonyl( $\eta^5$ -cyclopentadienyl)propionyl[tris(4-methoxyphenyl)phosphane- $\kappa P$ ]molybdenum(II) dichloromethane solvate,  $[\text{Mo}(\text{C}_5\text{H}_5)(\text{C}_3\text{H}_5\text{O})(\text{C}_{21}\text{H}_{21}\text{O}_3\text{P})(\text{CO})_2]\cdot\text{CH}_2\text{Cl}_2$ , (3), have been prepared from the corresponding ethyl complexes *via* phosphine-induced migratory insertion. These complexes exhibit four-legged piano-stool geometries with molecular structures quite similar to each other and to related acetyl complexes. The extended structures of the three complexes differ somewhat, with the *para* substituent of the triarylphosphine of (2) (fluoro) or (3) (methoxy) engaging in non-classical C–H···F or C–H···O hydrogen-bonding interactions. The structure of (3) exhibits modest disorder in the position of one Cl atom of the dichloromethane solvent, which was modeled with two sites showing approximately equivalent occupancies [0.532 (15) and 0.478 (15)].

## 1. Chemical context

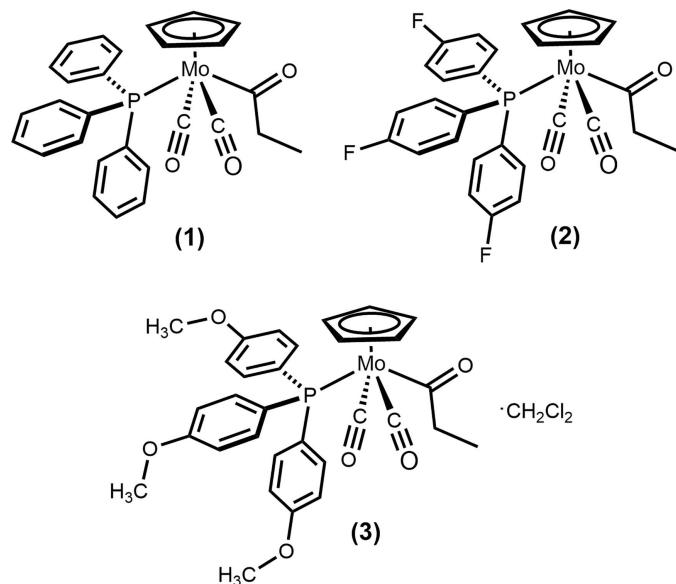

Cyclopentadienylmolybdenum(II) complexes featuring carbonyl ligands commonly adopt ‘four-legged piano-stool’ geometries (Barnett & Slocum, 1972; Kubacek *et al.*, 1982), and those featuring alkyl co-ligands readily undergo migratory insertion to afford Mo<sup>II</sup> acyl complexes upon exposure to phosphines (Barnett & Treichel, 1967; Butler *et al.*, 1967). The effect of changing phosphine substituents on this reaction is well established, with bulkier phosphines enhancing the rates of subsequent deinsertion from the acyl complexes, a net decarbonylation (Barnett, 1969; Barnett & Pollmann, 1974). Most complexes of the type  $\text{Mo}(\text{C}_5\text{H}_5)(\text{CO})_2(\text{PR}_3)(\text{COR})$  feature acetyl ligands, though there are limited examples of other acyl complexes that have been structurally characterized (Michelini-Rodriguez *et al.*, 1993; Murshid *et al.*, 2016).

We have previously reported synthetic details and solid-state structures for a number of Mo<sup>II</sup> acetyl complexes of the type described above (Whited & Hofmeister, 2014; Whited *et al.*, 2012, 2014), examining the effect of changing phosphine substituents on local and supramolecular features. Consistent with reports on decarbonylation reactivity, we have found that the primary impact on molecular structure is observed in the Mo–P bond lengths, with some changes in P–Mo–C bond

angles as a result of sterics. Use of tri(2-furyl)phosphine, which features heteroatoms as potential hydrogen-bond acceptors, leads to an unusual structure with the acetyl oriented down, away from the cyclopentadienyl ring rather than up toward it as observed in other cases (Whited *et al.*, 2013), and a similar effect was observed by incorporation of a Lewis-acidic manganese unit to interact with the acetyl ligand (Adatia *et al.*, 1986). Recent use of other potentially hydrogen-bonding phosphine ligands did not lead to the same solid-state effect (Anstey *et al.*, 2020).

We were interested in extending earlier studies to higher-order alkyl groups at molybdenum, and in this report we describe the synthesis and solid-state structures of related Mo<sup>II</sup> propionyl complexes derived from an ethyl precursor and supported by triarylphosphine ligands differing in their *para* substitution ( $-H$ ,  $-F$ , and  $-OCH_3$ ). Although substitution

of phosphine aryl groups with electron-withdrawing or -donating groups minimally affects local structure, the supramolecular organization is substantially affected by non-classical hydrogen-bonding to the fluoro and methoxy groups in (2) and (3), respectively.

## 2. Structural commentary

The molecular structures of **(1)**, **(2)**, and **(3)** are illustrated in Figs. 1–3. All complexes exhibit an overall structure common for CpMo acetyl complexes of this type, with *trans*-disposed carbonyl ligands. As previously observed for most related acetyl complexes, the acyl C=O points up toward the Cp ring. In the case of **(1)**, this phenomenon could be rationalized by presence of short C4–H4A···O1 (2.672 Å) and C4–

H4B $\cdots$ O2 (2.639  $\text{\AA}$ ) contacts involving the carbonyl ligands that are enabled when the acyl points up. However, the variation of the Mo1—C3—C4—C5 torsion angle across the series [175.31 (12) $^\circ$  for (1), 172.61 (18) $^\circ$  for (2), and 137.17 (10) $^\circ$  for (3)] argues against the general importance of such an interaction.

Selected geometric parameters for (1), (2), and (3) are presented in Tables 1–3. Complex (2) crystallized with two nearly equivalent molecules in the asymmetric unit, so geometric parameters are presented for both. In general, the

three complexes are nearly identical, as might be expected based on the dominant role of sterics in determining structure and the fact that the steric profiles of the three triarylphosphine ligands are identical. The Mo—P bond length in (2) [2.4692 (4)  $\text{\AA}$  (avg)] is slightly shorter than in (1) or (3) [2.4816 (4) and 2.4745 (3)  $\text{\AA}$ , respectively], which may be related to stronger  $\pi$ -backbonding to the tris(4-fluorophenyl)phosphine ligand. Stronger backbonding is supported by the observation by infrared spectroscopy of slightly higher-energy carbonyl stretching vibrations for (2) [ $\nu(\text{CO})_{\text{avg}} = 1897 \text{ cm}^{-1}$ ] compared with (1) and (3) [ $\nu(\text{CO})_{\text{avg}} = 1893 \text{ cm}^{-1}$  for (1), 1890  $\text{cm}^{-1}$  for (3)]. Geometric parameters for all complexes are quite similar to those for the related triphenylphosphine-supported CpMo acetyl complex (Churchill & Fennessey, 1968).

### 3. Supramolecular features

In spite of the similarities among (1), (2), and (3) in their molecular structures, the *para* substituent of the triarylphosphine ligand [H for (1), F for (2), OCH<sub>3</sub> for (3)] plays an important role in determining the extended structure. The extended structure of (1) is dominated by non-classical C—H $\cdots$ O interactions involving its carbonyl ligands. A short C—H $\cdots$ O interaction between O2 and H12 of a phenyl ring (2.36  $\text{\AA}$ ) joins molecules of (1) into centrosymmetrical dimers that are organized into chains along [010] by intermolecular C15—H15 $\cdots$ Cg4 (2.952  $\text{\AA}$ , where Cg4 represents the centroid of the C23—C28 ring) and intramolecular O2 $\cdots$ Cg4 (3.295  $\text{\AA}$ ) interactions (Fig. 4, Table 4). These chains are linked into sheets parallel to (10 $\bar{1}$ ) through another set of non-classical

C—H $\cdots$ O interactions (2.60  $\text{\AA}$ ) between O1 of the other carbonyl ligand and H6 from a cyclopentadienyl ligand (Fig. 5).

The tris(4-fluorophenyl)phosphine-supported derivative (2) features two nearly equivalent molecules in the asymmetric unit exhibiting a non-classical C—H $\cdots$ O interaction between O6 of a propionyl ligand and H15 from a phenyl ring (2.59  $\text{\AA}$ ) and a C—H $\cdots$ F close contact between F3 and H53 (2.60  $\text{\AA}$ ). These pairs of molecules are joined into chains along [001] by C34—H34 $\cdots$ O1 hydrogen bonding (2.38  $\text{\AA}$ , Fig. 6, Table 5)).

The molecules are further organized parallel to (010) by C—H $\cdots$ F close contacts between F4 and H49 (2.55  $\text{\AA}$ ) and C—H $\cdots$ O interactions between O3 and H55 (2.53  $\text{\AA}$ ) (Fig. 7), then further joined along [010] by C—F $\cdots$  $\pi$  interactions ( $F5\cdots Cg4 = 3.17 \text{\AA}$ , where  $Cg4$  represents the centroid of the C23—C38 ring).

Like complex (1), complex (3) is joined into centrosymmetrical dimers by a C—H $\cdots$ O interaction involving a carbonyl ligand (C8—H8 $\cdots$ O1, Table 6), and these are linked into chains along [110] through an additional C—H $\cdots$ O interaction between the propionyl oxygen and a cyclopentadienyl ligand (Fig. 8). Additional C31—H31B $\cdots$ O5 interactions along [110], involving a methoxy group from the phosphine ligand, join the molecules into a network parallel to (001). This further set of interactions involving methoxy groups, as well as important close contacts involving the dichloromethane solvent, are depicted in Fig. 9.

#### 4. Database survey

The current version of the Cambridge Structural Database (Version 5.41, updated August 2020; Groom *et al.*, 2016) has fourteen entries corresponding to molybdenum acyl complexes of the general form  $\text{Mo}(\text{C}_5\text{H}_5)(\text{CO})_2(\text{PR}_3)(\text{COR})$ . The *trans*-dicarbonyl structure, as observed for (1)–(3), is preferred except in cases where the phosphine and acyl ligands are covalently linked, forcing them to be *cis* (Adams *et al.*, 1991; Mercier *et al.*, 1993; Yan *et al.*, 2009).

#### 5. Synthesis and crystallization

**CpMo(CO)<sub>3</sub>(CH<sub>2</sub>CH<sub>3</sub>)**. This compound was prepared by modification of the method used of Gladysz *et al.* (1979), as previously reported by Whited & Hofmeister (2014) and Anstey *et al.* (2020). In a 20 ml scintillation vial equipped with a flea-sized stir bar,  $[\text{CpMo}(\text{CO})_3]_2$  (0.1908 g, 0.39 mmol) was dissolved in THF (10 ml). Sodium triethylborohydride (0.87 mL of 1.0 M solution in THF, 0.87 mmol) was added dropwise by syringe with vigorous stirring, leading to an immediate color change from purple to green-yellow with evolution of H<sub>2</sub> gas. The reaction was allowed to proceed with stirring for 20 min, and an excess of iodoethane (0.098 mL, 1.2 mmol) was added dropwise with stirring and the reaction was allowed to proceed for 6 h. Volatiles were removed *in vacuo* to afford a yellow–brown film that was stored at 238 K for 1 week. The solid was extracted with pentane (4 × 10 mL) and filtered through a 1 cm pad of activated alumina to afford a yellow solution, and removal of solvent *in vacuo* afforded **CpMo(CO)<sub>3</sub>(CH<sub>2</sub>CH<sub>3</sub>)** as a pure yellow powder (0.131 g, 61%). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>): δ 5.28 (*s*, 5H, Cp ring), 1.72 (*q*, <sup>3</sup>J<sub>HH</sub> = 7.4 Hz, 2H,  $-\text{CH}_2\text{CH}_3$ ), 1.45 (*t*, <sup>3</sup>J<sub>HH</sub> = 7.4 Hz, 3H,  $-\text{CH}_2\text{CH}_3$ ). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>): δ 239.9 (Mo–CO), 227.8 (Mo–CO), 93.0 (Cp ring), 20.4 (Mo–CH<sub>2</sub>CH<sub>3</sub>) –3.7 (Mo–CH<sub>2</sub>CH<sub>3</sub>). IR (CH<sub>2</sub>Cl<sub>2</sub>, NaCl, cm<sup>−1</sup>) ν(CO): 2015, 1921 (split).

**CpMo(CO)<sub>2</sub>(PPh<sub>3</sub>)(COCH<sub>2</sub>CH<sub>3</sub>)** (1). In an inert-atmosphere glove box, CpMo(CO)<sub>3</sub>(CH<sub>2</sub>CH<sub>3</sub>) (0.0803 g, 0.293 mmol) and triphenylphosphine (0.115 g, 0.440 mmol, 1.5 equiv) were dissolved in acetonitrile (5 mL) in a 20 mL scintillation vial equipped with a flea-sized stir bar. The mixture was stirred for 1 week, during which time a bright-yellow precipitate formed. The yellow solid was isolated by filtration and washed with pentane (2 × 5 mL), then dried *in vacuo* to afford pure **1**. Yellow crystals of **1** suitable for X-ray diffraction were obtained from a concentrated dichloromethane solution by vapor cross diffusion with pentane at 238 K. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>): δ 7.50–7.30 (*m*, 15H, PPh<sub>3</sub>), 5.00 (*d*, *J* = 1.2 Hz, 5H, C<sub>5</sub>H<sub>5</sub>), 3.03 (*q*, <sup>3</sup>J<sub>HH</sub> = 7.2 Hz, 2H, C(O)CH<sub>2</sub>CH<sub>3</sub>), 0.90 (*t*, <sup>3</sup>J<sub>HH</sub> = 7.2 Hz, 3H, C(O)CH<sub>2</sub>CH<sub>3</sub>). <sup>13</sup>C{<sup>1</sup>H} NMR (101 MHz, CDCl<sub>3</sub>): δ 267.7 (*d*, <sup>2</sup>J<sub>CP</sub> = 11 Hz, Mo–COEt), 238.8 (*d*, <sup>2</sup>J<sub>CP</sub> = 24 Hz, Mo–CO), 135.7 (*d*, <sup>1</sup>J<sub>CP</sub> = 44 Hz, *ipso*-C of PPh<sub>3</sub>), 133.2 (*d*, <sup>2</sup>J<sub>CP</sub> = 11 Hz, *ortho*-C of PPh<sub>3</sub>), 130.5 (*d*, <sup>4</sup>J<sub>CP</sub> = 2 Hz, *para*-C of PPh<sub>3</sub>), 128.6 (*d*, <sup>3</sup>J<sub>CP</sub> = 11 Hz, *meta*-C of PPh<sub>3</sub>), 96.7 (Cp ring), 58.1 (Mo–COCH<sub>2</sub>CH<sub>3</sub>), 10.1 (Mo–COCH<sub>2</sub>CH<sub>3</sub>). <sup>31</sup>P{<sup>1</sup>H} NMR

**CpMo(CO)<sub>2</sub>(P(4-FPh)<sub>3</sub>)(COCH<sub>2</sub>CH<sub>3</sub>)** (2). In an inert-atmosphere glove box, CpMo(CO)<sub>3</sub>(CH<sub>2</sub>CH<sub>3</sub>) (0.0997 g, 0.36 mmol) and tris(4-fluorophenyl)phosphine (0.17 g, 0.55 mmol, 1.5 equiv) were dissolved in acetonitrile (5 mL) in a 20 mL scintillation vial equipped with a flea-sized stir bar. The mixture was stirred for 1 week, causing a color change to orange, but without formation of any precipitate. Solvent was removed *in vacuo*, causing precipitation of a yellow solid that was isolated by filtration and washed with pentane (2 × 3 mL) to afford the desired product **2** (0.12 g, 56%). methyl, methylene, and cyclopentadienyl groups, respectively, and with  $U_{\text{iso}}(\text{H}) = k \times U_{\text{eq}}(\text{C})$ ,  $k = 1.2$  for cyclopentadienyl, phenyl, and methylene groups and 1.5 for methyl groups. Methyl group H atoms were allowed to rotate in order to find the best rotameric conformation.

A small number of intense low-angle reflections [three for (1); seven for (2); five for (3)] are missing from these high-quality data sets due to the arrangement of the instrument with a conservatively sized beam stop. The large number of reflections in the data sets (and the Fourier-transform relationship of intensities to atoms) ensures that no particular bias has been introduced.

The structure of (3) exhibits modest disorder in the position of Cl1 of the dichloromethane solvent, which was modeled with two sites showing approximately equivalent occupancies [0.532 (15) for Cl1A, 0.468 (15) for Cl1B].

#### Special details

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

## Special details

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
