# Redetermination of the crystal structures of rareearth trirhodium diboride $R E R h_{3} B_{2}(R E=P r, N d$ and Sm ) from single-crystal X-ray data 

Makoto Tokuda,* Kunio Yubuta, Toetsu Shishido and Kazumasa Sugiyama

Institute for Materials Research, Tohoku University, 2-1-1 Katahira, Aoba-ku, Sendai 980-8577, Japan. *Correspondence e-mail: makoto.tokuda.b7@tohoku.ac.jp

The crystal structures of the rare-earth $(R E)$ trirhodium diborides praseodymium trirhodium diboride, $\operatorname{PrRh}_{3} \mathrm{~B}_{2}$, neodymium trirhodium diboride, $\mathrm{NdRh}_{3} \mathrm{~B}_{2}$, and samarium trirhodium diboride, $\mathrm{SmRh}_{3} \mathrm{~B}_{2}$, were refined on the basis of single-crystal X-ray diffraction data. The crystal chemistry of $R E R h_{3} \mathrm{~B}_{2}$ ( $R E: \mathrm{Pr}, \mathrm{Nd}$, and Sm ) compounds has previously been analyzed mainly on the basis of powder samples [Ku et al. (1980). Solid State Commun. 35, 91-96], and no structural investigation by single-crystal X-ray diffraction has been reported so far. The crystal structures of the three hexagonal $R E R h_{3} B_{2}$ compounds are isotypic with that of $\mathrm{CeRh}_{3} \mathrm{~B}_{2} ; R E, \mathrm{Rh}$ and B sites are situated on special positions with site symmetry $6 / \mathrm{mmm}$ (Wyckoff position $1 a$ ), mmm ( 3 g ) and $\overline{6} m 2$ ( $2 c$ ), respectively. In comparison with the previous powder X-ray study of hexagonal $R E R h_{3} B_{2}$, the present redetermination against single-crystal X-ray data has allowed for the modeling of all atoms with anisotropic displacement parameters (ADPs). The ADPs of the Rh atom in each of the structures result in an elongated displacement ellipsoid in the direction of the stacking of the Rh kagomé-type layer. The features of obtained ADPs of atoms are discussed in relation to $R E \mathrm{Rh}_{3} \mathrm{~B}_{2}$-type and analogous structures.

## 1. Chemical context

$\mathrm{CeCo}_{3} \mathrm{~B}_{2}$-type $R E \mathrm{Rh}_{3} \mathrm{~B}_{2} \quad(R E=$ rare-earth element $)$ compounds exhibit anomalous ferromagnetic properties (Malik et al., 1983; Yamada et al., 2004), and the unit-cell parameters of these compounds have been reported using powder X-ray diffraction (XRD) data (Ku et al., 1980; Ku \& Meisner, 1981). Higashi et al. (1987) analyzed the crystal structure of $\mathrm{CeRh}_{3} \mathrm{~B}_{2}$ by using single-crystal XRD data and discussed the characteristics of the anisotropic atomic displacement parameters (ADP) of atoms in $\mathrm{CeRh}_{3} \mathrm{~B}_{2}$ in relation to the structure. We report here the results of structural refinements using single crystals of $R E R h_{3} \mathrm{~B}_{2}(R E=\mathrm{Pr}, \mathrm{Nd}$, and Sm$)$ grown by the arc-melting method.

## 2. Structural commentary

The crystal structures of hexagonal $R E \mathrm{Rh}_{3} \mathrm{~B}_{2}(R E ; \mathrm{La}-\mathrm{Gd})$ compounds are isotypic with $\mathrm{CeCo}_{3} \mathrm{~B}_{2}$ and crystallize in spacegroup type $P 6 / \mathrm{mmm}$ (Kuz'ma et al., 1969). The $\mathrm{CeCo}_{3} \mathrm{~B}_{2}$ type of structure is ordered and can be derived from the $\mathrm{CaCu}_{5}$ type of structure, whereby two distinct atoms ( Rh and B ) occupy the corresponding Cu sites. Each B atom is surrounded by six Rh atoms, forming a trigonal prism. Such [ $\mathrm{BRh}_{6}$ ]
trigonal prisms constitute a honeycomb structure and $R E$ atoms are accommodated at the centers of the twelve [ $R E \mathrm{Rh}_{12}$ ] hexagonal prisms, as shown in Fig. 1. The $R E R h_{3} \mathrm{~B}_{2}$ type of structure can also be described as being built up of kagomé layers of Rh atoms stacked along the $c$ axis with an $\alpha \alpha$ stacking sequence and with B and $R E$ atoms at the centers of the Rh triangular and hexagonal prisms, respectively.

The unit-cell parameters $a$ and $c$ and the unit-cell volume $V$ of $R E R h_{3} \mathrm{~B}_{2}(R E=\mathrm{La}-\mathrm{Sm})$ compounds are shown in Fig. 2. The decrease in unit-cell volume results from the lanthanide contraction. The lattice parameters $a$ and $c$ decrease and increase, respectively. These anisotropic changes in the unitcell parameters are consistent with those of a previous report using powder XRD analysis (Malik et al., 1983).

The anisotropic change in the unit-cell parameters can be explained by the change in interatomic distances due to the lanthanide contraction. The ranges of $\mathrm{B}-\mathrm{Rh}$ and $R E-\mathrm{Rh}$ distances are 2.2129 (1)-2.2151 (1) $\AA$ and 3.1370 (1)3.1447 (1) $\AA$ (Table 1), respectively, which are close to the values of the sums of the atomic radii $\left(r_{\mathrm{Rh}}=1.35 \AA, r_{\mathrm{B}}=\right.$ $0.85 \AA, r_{\mathrm{Pr}}=1.84 \AA, r_{\mathrm{Nd}}=1.83 \AA$, and $r_{\mathrm{Sm}}=1.81 \AA$; Daane et al., 1954; Spedding et al., 1956; Zachariasen, 1973). The RERh interatomic distances decrease due to the effect of the lanthanoid contraction. $\mathrm{Rh}-\mathrm{Rh}$ interatomic distances in the $a b$ plane also decrease with a decrease in $R E-\mathrm{Rh}$ distances. By contrast, the $\mathrm{Rh}-\mathrm{Rh}$ interatomic distances along the $c$ axis increase. This causes the $\left[R E R h_{12}\right]$ hexagonal and $\left[\mathrm{BRh}_{6}\right]$ trigonal prisms to shrink horizontally and stretch vertically, resulting in decreases of the volumes of the hexagonal and trigonal prisms. Therefore, the unit-cells of $R E R h_{3} B_{2}$ compounds change anisotropically, suggesting that the unitcell changes elastically in response to the substitution of elements of different sizes at the $R E$ site.

Figure 1
Structure of $R E R h_{3} \mathrm{~B}_{2}$ compounds (space group: $P 6 / \mathrm{mmm}$ ) as viewed along the $c$ axis. B and $R E$ atoms settle in the center of the trigonal and hexagonal prisms, respectively.

Table 1
Selected bond lengths $(\AA)$ in $R E R h_{3} B_{2}(R E=\operatorname{Pr}, N d$ and $S m)$.

|  | $\mathrm{PrRh}_{3} \mathrm{~B}_{2}$ | $\mathrm{NdRh}_{3} \mathrm{~B}_{2}$ | $\mathrm{SmRh}_{3} \mathrm{~B}_{2}$ |
| :--- | :--- | :--- | :--- |
| $R E-R E \times 2$ | $3.1084(1)$ | $3.1107(1)$ | $3.1190(1)$ |
| $R E-R E \times 6$ | $5.4676(4)$ | $5.4527(3)$ | $5.4438(3)$ |
| $R E-\mathrm{Rh} \times 12$ | $3.1447(1)$ | $3.1388(1)$ | $3.1370(1)$ |
| $R E-\mathrm{B} \times 6$ | $3.1557(2)$ | $3.1481(1)$ | $3.1430(1)$ |
| $\mathrm{B}-\mathrm{Rh} \times 6$ | $2.2151(1)$ | $2.2129(1)$ | $2.2140(1)$ |
| $\mathrm{B}-\mathrm{B} \times 3$ | $3.1084(1)$ | $3.1107(1)$ | $3.1190(1)$ |
| $\mathrm{B}-\mathrm{B} \times 3$ | $3.1567(2)$ | $3.1481(1)$ | $3.1430(1)$ |
| $\mathrm{Rh}-\mathrm{Rh} \times 4$ | $2.7338(2)$ | $2.7264(1)$ | $2.7219(1)$ |
| $\mathrm{Rh}-\mathrm{Rh} \times 2$ | $3.1084(1)$ | $3.1107(1)$ | $3.1190(1)$ |

The obtained ADPs for each atom are summarized in Table 2. The displacement ellipsoid of the Rh atom shows a larger anisotropy than those of the B and $R E$ atoms, as shown in Fig. 3. The $U_{33}$ of Rh atoms is approximately 2.1-2.6 times

Figure 2

larger than $U_{11}$, which means that the displacement ellipsoids of Rh atoms are elongated along the $c$ axis. The displacement ellipsoids of Rh atoms with large anisotropy correspond to the anisotropic electric resistivity of $R E R h_{3} \mathrm{~B}_{2}$ compounds (Yamada et al., 2004; Obiraki et al., 2006). The ADPs of $R E$ atoms are described as displacement ellipsoids suppressed in the $c$ axis $\left(U_{11}<U_{33}\right)$. The feature of displacement ellipsoids of Rh and $R E$ atoms is attributed to the unusually short $R E-R E$ interatomic distances of 3.1084 (1)-3.1190 (1) $\AA$, which are much shorter ( $15 \%$ ) than the distance in the metal $\mathrm{Pr}, \mathrm{Nd}$, and Sm with hexagonal close-packed structures, (i.e., 3.67, 3.66, and $3.62 \AA$, respectively). The short $R E-R E$ interatomic distance is a common feature of the $\mathrm{CeCo}_{3} \mathrm{~B}_{2}$ type of structure. Anisotropy of electric or thermal conductivity is also expected to be observed in $\mathrm{CeRh}_{3} \mathrm{~B}_{2}$ compounds.

The obtained anisotropic ADPs of each atom in the structures of $R E \mathrm{Rh}_{3} \mathrm{~B}_{2}$ compounds can be discussed in terms of the nucleation of interstitial atoms or layers in $\operatorname{PrRh}_{4.8} \mathrm{~B}_{2}$ (Higashi et al., 1988). Higashi et al. (1988) discovered a new layered structure, namely, $\operatorname{PrRh}_{4.8} \mathrm{~B}_{2}$, which is regarded as a stacking variant of a modified $\mathrm{PrRh}_{3} \mathrm{~B}_{2}$ structure. The interstitial single Rh layer is positioned between the Rh kagomé layers of the

Figure 3
Displacement ellipsoids of each atom in $\mathrm{NdRh}_{3} \mathrm{~B}_{2}$, with displacement ellipsoids drawn at the $99 \%$ probability level.
modified $\mathrm{PrRh}_{3} \mathrm{~B}_{2}$ blocks. The displacement ellipsoid in the stacking direction of the Rh atom in the $\mathrm{PrRh}_{3} \mathrm{~B}_{2}$ structure implies that the Rh kagomé layer in $\mathrm{PrRh}_{3} \mathrm{~B}_{2}$ could be a base for the nucleation of interstitial atoms or layers. The appearance of disordered $\mathrm{La}_{1-x} \mathrm{Rh}_{3} \mathrm{~B}_{2}$ type and/or $\mathrm{Nd}_{1-x} \mathrm{Rh}_{x} \mathrm{Rh}_{3} \mathrm{~B}_{2}$ type of structures (Ohtani et al., 1983; Vlasse et al., 1983; Ku et al., 1985) might be associated with the anisotropic ADPs of Rh and $R E$ atoms.

## 3. Synthesis and crystallization

$R E \mathrm{Rh}_{3} \mathrm{~B}_{2}(R E=\mathrm{Pr}, \mathrm{Nd}$, and Sm$)$ single crystals were grown using the arc-melting method. The starting materials used were $R E$ elements ( $99.9 \%$ ), along with Rh ( $99.95 \%$ ), and B $(99.5 \%)$. They were weighed at an atomic ratio of $(R E+3 R \mathrm{~h}+2 \mathrm{~B})$, and the mixtures of the starting materials were placed in an argon-arc melting furnace (ACM-01, Diavac). Each product was remelted three times to improve homogeneity. The grown crystals were composed of homogeneous $R E \mathrm{Rh}_{3} \mathrm{~B}_{2}$, and the atomic ratio $\mathrm{Rh} / R E$ was confirmed to be 3.00 by energy dispersive X-ray spectroscopy.

## 4. Refinement details

Crystal data, data collection and structure refinement details are summarized in Table 3. A reciprocal space plot using all reflection data was in good agreement with the hexagonal lattice ( $a \simeq 5 \AA$ and $c \simeq 3 \AA$ ), and there was no evidence of superstructure reflections. The refinement was conducted under the assumption that the space group type was $P 6 / \mathrm{mmm}$, as reported by Ku et al. (1980). Based on structural reports of $\mathrm{La}_{1-x} \mathrm{Rh}_{3} \mathrm{~B}_{2}$ and $\mathrm{Nd}_{1-x} \mathrm{Rh}_{x} \mathrm{Rh}_{3} \mathrm{~B}_{2}$, we determined whether Rh substitution and vacancies at the $R E$ site were possible; however, the results were negative. Therefore, we concluded that the $R E$ sites were completely occupied by $R E$ elements. A correction for isotropic extinction was applied during the least-squares refinements. The final refinements were performed by applying anisotropic ADPs to each atom. The remaining electron densities located $0.7-0.6 \AA$ around rhodium and $R E$ heavy elements are censoring effects caused by the finite Fourier series.

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
