The synthesis and crystal structure of a monoclinic polymorph of 2-amino-5chlorobenzophenone oxime, $\mathrm{C}_{13} \mathrm{H}_{11} \mathrm{ClN}_{2} \mathrm{O}$, are presented. The molecular conformation results from twisting of the phenyl and 2 -amino-5-chloro benzene rings attached to the oxime group, which subtend a dihedral angle of $80.53(4)^{\circ}$. In the crystal, centrosymmetric dimers are formed as a result of pairs of strong $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds. A comparison is made to a previously known triclinic polymorph, including differences in atom-atom contacts obtained via a Hirshfeld-surface analysis.

## 1. Chemical context

2-Amino-5-chlorobenzophenone is an ecologically friendly cross-linking agent. Benzophenone and related compounds have been reported to act as anti-allergic, anti-inflammatory, anti-asthmatic, and anti-anaphylactic agents (Evans et al., 1987; Wiesner et al., 2002; Sieron et al., 2004). Benzophenone derivatives are widely used in sunscreen lotions, offering UVA and UV-B protection (Deleu et al., 1992). 2-Amino-5chlorobenzophenone is used to produce intermediates for the synthesis of oxazolam drugs and intermediates for psychotherapeutic agents, such as chlorodiazepoxide and diazepam (Sternbach \& Reeder, 1961a,b). 2-Aminobenzophenone and its derivatives have importance because of their applications in heterocyclic synthesis and medicines (Walsh, 1980) and are also used as anti-mitotic agents (Liou et al., 2002). The growth and characterization of 2-amino-5-chlorobenzophenone single crystals was reported by Mohamed et al. (2007). Synthesis, herbicidal evaluation and structure-activity relationships of some benzophenone oxime ether derivatives was reported by Ma et al. (2015). The synthesis, physicochemical, and biological evaluation of 2-amino-5-chlorobenzophenone derivatives as potent skeletal muscle relaxants was reported by Singh et al. (2015). Details of synthetic methodologies and the pharmacological significance of 2-aminobenzophenones as versatile building blocks was published by Chaudhary et al. (2018). The reactivity of oximes for diverse methodologies and synthetic applications was recently reported by Rykaczewski et al. (2022). In view of the general importance of benzophenone derivatives and those of 2 -amino-5-chlorobenzophenone in particular, this paper reports the 90 K crystal

structure and Hirshfeld-surface studies of a monoclinic form of 2-amino-5-chlorobenzophenone oxime, $\mathrm{C}_{13} \mathrm{H}_{11} \mathrm{ClN}_{2} \mathrm{O}$, mon-2A-5CBO. A triclinic polymorph was recently published as a CSD communication (refcode REZSIB) by Lanzilotto, Housecroft et al. (2018). Some comparisons between the two crystal structures are presented.

## 2. Structural commentary

The overall conformation of the mon-2A-5CBO molecule (Fig. 1) is determined by torsion angles about the $\mathrm{C} 6-\mathrm{C} 7$ and $\mathrm{C} 7-\mathrm{C} 8$ bonds that connect the chloroaniline and phenyl rings to the oxime carbon, C 7 . These are held in check by an intramolecular hydrogen bond, $\mathrm{N} 1-\mathrm{H} 1 N A \cdots \mathrm{O} 1\left[d_{D \cdots A}=\right.$ 2.8875 (19) $\AA$, Table 1]. These torsion angles result in a dihedral angle between the two rings of $80.53(4)^{\circ}$. The

Figure 1
An ellipsoid plot ( $50 \%$ probability) of mon-2A-5CBO. The intramolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond is shown as a dashed line.

Table 2
Comparison of conformation-defining torsion and dihedral angles ( ${ }^{\circ}$ ) in mon-2A-5CBO and CSD entry REZSIB.

|  | mon-2A-5CBO | REZSIB $^{a, b}$ |
| :--- | :---: | ---: |
| Torsion angle |  |  |
| N1-C1-C6-C7 | $-1.3(2)$ | -5.6 |
| C1-C6-C7-N2 | $60.8(2)$ | 56.7 |
| C6-C7-N2-O1 | $0.5(2)$ | 7.8 |
| Dihedral angle | $80.53(4)$ | 75.82 |
| C1-C6/C8-C13 |  |  |

Notes: (a) The numbering scheme in REZSIB is different from mon-2A-5CBO; (b) Values from Mercury (Macrae et al., 2020), therefore there are no SUs.
conformation defining torsion and dihedral angles are gathered in Table 2 along with those of the triclinic polymorph, REZSIB (Lanzilotto, Housecroft et al., 2018). The conformations of the $2 \mathrm{~A}-5 \mathrm{CBO}$ molecules in the two polymorphs are quite similar, as shown by the overlay plot in Fig. 2. The r.m.s. deviation obtained from a weighted least-squares fit of all nonhydrogen atoms using OFIT in SHELXTL-XP (Sheldrick, 2008) is only $0.1315 \AA$, with the largest deviation being 0.267 Å for C12.

## 3. Supramolecular features

The main supramolecular constructs in the mon-2A-5CBO crystal structure are $R_{2}^{2}(6)$ centrosymmetric dimers that result from pairs $\left(\mathrm{O} 1-\mathrm{H} 1 O \cdots \mathrm{~N} 2^{\text {inv }}\right.$ and $\mathrm{O}^{\text {inv }}-\mathrm{H} 1 O^{\text {inv }} \cdots \mathrm{N} 2$, inv $=$ $1-x, 1-y, 1-z$ ) of strong hydrogen bonds $\left[d_{D \cdots A}=\right.$ 2.7411 (16) $\AA$, Table 1]. These are shown as dashed lines in Fig. 3 along with a representation of the Hirshfeld surface, as generated by CrystalExplorer (Spackman et al., 2021), on which the hydrogen bonds are responsible for the prominent red spots. Similar dimer motifs are present in REZSIB. The most striking difference in packing between the two polymorphs is that REZSIB exhibits slip-stacked $\pi-\pi$ overlap

Figure 2
A least-squares fit overlay of mon-2A-5CBO and the triclinic polymorph REZSIB (red).

Figure 3
A partial packing plot of mon-2A-5CBO viewed approximately down the $b$-axis showing the Hirshfeld surface (left) and the $R_{2}^{2}(6)$ centrosymmetric dimer formed by pairs of $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds (dashed lines and prominent red spots).
[interplanar separation $=3.340(2) \AA$, centroid-centroid distance $=3.897(2) \AA]$ of inversion-related $(1-x,-y, 1-z)$ chloroaniline rings, whereas mon-2A-5CBO does not. Hirshfeld surface 2D-fingerprint plots for mon-2A-5CBO are shown in Fig. 4 and the differences in contacts between the polymorphs are summarized in Table 3.

## 4. Database survey

A survey of the Cambridge Structural Database (CSD: v5.43 including all updates through November 2022; Groom et al., 2016) returned 5507 hits for a search fragment consisting of unsubstituted benzophenone. A search using benzophenone oxime as the probe, however, returned only 35 entries. Of these, ten have a nitrogen-bound functional group at the ortho-position of one of the benzene rings, while six have 'any halogen' attached at one of the meta-positions. In only two structures is this halogen a chlorine atom: YIFCIC (Lanzi-

lotto, Prescimone et al., 2018), $\mathrm{C}_{15} \mathrm{H}_{11} \mathrm{Cl}_{2} \mathrm{FN}_{2} \mathrm{O}_{2}$, systematic name 2 -chloro- $N$-\{4-chloro-2-[(2-fluorophenyl)(hydroxyimino)methyl]phenyl\}acetamide and REZSIB (Lanzilotto, Housecroft et al., 2018), the triclinic ( $P \overline{1}$ ) polymorph of the monoclinic ( $P 2_{1} / n$ ) 2A-5CBO crystal structure described herein.

Some other related crystal structures include 2-amino-5chlorobenzophenone as monoclinic (NUVFAL; VascoMendez et al., 1996) and triclinic (NUVFAL02; Javed et al., 2018) polymorphs, benzophenone oxime (XULKUK; Sharutin et al., 2002), and 2-benzoyloxy-5-methylbenzophenone (OCAMOV; Sieron et al., 2004).

## 5. Synthesis and crystallization

The synthesis of 2A-5CBO (Fig. 5) was by a modification of Beckmann's conversion of benzophenone to benzophenone oxime (Beckmann, 1886). In a 100 ml round-bottom flask fitted with a magnetic stirrer was placed a mixture of $100 \mathrm{mmol}(23.2 \mathrm{~g})$ of 2-amino-5-chlorobenzophenone, $120 \mathrm{mmol}(7 \mathrm{~g})$ of hydroxylamine hydrochloride in 10 ml of ethanol. To this stirred mixture, 0.5 g of sodium hydroxide pellets was added in small portions. When the reaction became vigorous, the flask was placed in an ice bath. A condenser was attached to the flask and the mixture was refluxed for 5 minutes on a steam bath. The solution was cooled and poured into a beaker containing 5 ml of hydrochloric acid and crushed ice. This was stirred until a precipitate formed. After filtering the precipitate with suction and washing with cold distilled water, the product was spread out on filter paper and air dried. The yield was $87 \%$. X-ray quality crystals were obtained from methanol by slow evaporation (m.p.: 390-393 K).

## 6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 4. All hydrogen atoms were found in difference-Fourier maps. Those bound to carbon were subsequently included in the refinement using a riding model, with constrained distances fixed at $0.95 \AA$ and $U_{\text {iso }}(\mathrm{H})$ values set to $1.2 U_{\text {eq }}$ of the attached atom. The amine and oxime hydrogen atoms were refined freely.

## Special details

Experimental. The crystal was mounted using polyisobutene oil on the tip of a fine glass fibre, which was fastened in a copper mounting pin with electrical solder. It was placed directly into the cold gas stream of a liquid-nitrogen based cryostat (Hope, 1994; Parkin \& Hope, 1998).
Diffraction data were collected with the crystal at 90 K , which is standard practice in this laboratory for the majority of flash-cooled crystals.
Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
