When reacted in dry, degassed toluene,  $[\text{Ir}(\text{COD})\text{Cl}]_2$  (COD = cycloocta-1,5-diene) and 2 equivalents of 2-(di-*tert*-butylphosphinito)anthraquinone ( $^{t\text{Bu}}\text{POAQH}$ ) were found to form a unique tri-iridium compound consisting of one monoanionic dinuclear tri- $\mu$ -chlorido complex bearing one bidentate  $^{t\text{Bu}}\text{POAQ}$  ligand per iridium, which was charge-balanced by an outer sphere  $[\text{Ir}(\text{toluene})(\text{COD})]^{+}$  ion, the structure of which has not previously been reported. This product, which is a toluene solvate, namely, ( $\eta^2$ : $\eta^2$ -cycloocta-1,5-diene)( $\eta^6$ -toluene)iridium(I) tri- $\mu$ -chlorido-bis({3-[di-*tert*-butylphosphanyl]-oxy}-9,10-dioxoanthracen-2-yl)hydridoiridium(III) toluene monosolvate,  $[\text{Ir}(\text{C}_7\text{H}_8)(\text{C}_8\text{H}_{12})][\text{Ir}_2\text{H}_2(\text{C}_{22}\text{H}_{24}\text{O}_3\text{P})_2\text{Cl}_3]\cdot\text{C}_7\text{H}_8$  or  $[\text{Ir}(\text{toluene})(\text{COD})][\text{Ir}(\kappa-P, C-\text{t}^{\text{Bu}}\text{POAQ})(\text{H})_2(\mu-\text{Cl})_3]\cdot\text{toluene}$ , formed as small orange platelets at room temperature, crystallizing in the triclinic space group  $P\bar{1}$ . The cation and anion are linked *via* weak C—H···O interactions. The stronger intermolecular attractions are likely the offset parallel  $\pi$ – $\pi$  interactions, which occur between the toluene ligands of pairs of inverted cations and between pairs of inverted anthraquinone moieties, the latter of which are capped by toluene solvate molecules, making for  $\pi$ -stacks of four molecules each. The related ligand, 2-(di-*tert*-butylphosphinomethyl)-anthraquinone ( $^{t\text{Bu}}\text{PCAQH}$ ), did not form crystals suitable for X-ray diffraction under analogous reaction conditions. However, when the reaction was conducted in chloroform, yellow needles readily formed following addition of 1 atm of carbon monoxide. Diffraction studies revealed a neutral, dinuclear, di- $\mu$ -chlorido complex, di- $\mu$ -chlorido-bis(carbonyl-{3-[di-*tert*-butylphosphanyl]oxy}-9,10-dioxoanthracen-2-yl)hydridoiridium(I)),  $[\text{Ir}_2\text{H}_2(\text{C}_{22}\text{H}_{26}\text{O}_2\text{P})_2\text{Cl}_2(\text{CO})_2]$  or  $[\text{Ir}(\kappa-P, C-\text{t}^{\text{Bu}}\text{PCAQ})(\text{H})(\text{CO})(\mu-\text{Cl})_2]$ ,  $\text{Ir}_2\text{C}_{48}\text{H}_{54}\text{Cl}_2\text{O}_6\text{P}_2$ , again crystallizing in space group  $P\bar{1}$ . Offset parallel  $\pi$ – $\pi$  interactions between anthraquinone groups of adjacent molecules link the molecules in one dimension.

## 1. Chemical context

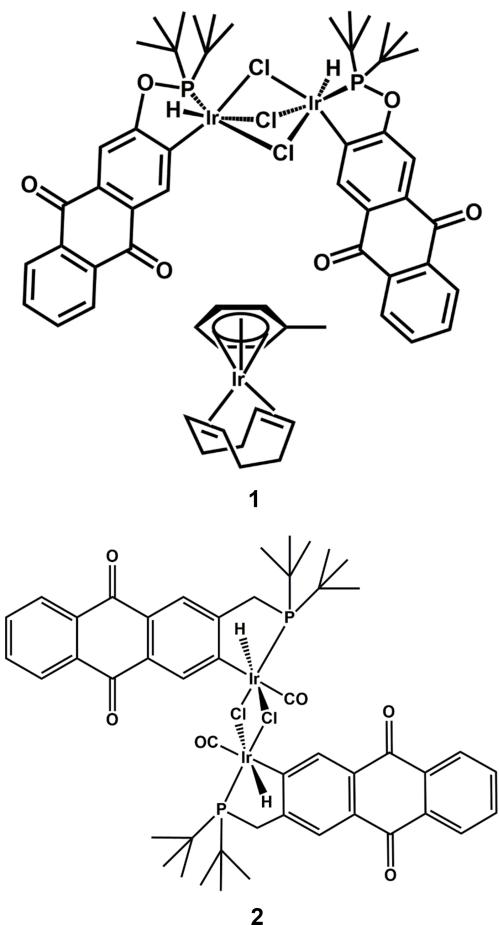

Tridentate, meridional ligands known as ‘pincers’ have become ubiquitous in organometallic chemistry, particularly in complexes of platinum group metals (Albrecht & van Koten, 2001), though many systems incorporating first-row transition metals now exist (Morales-Morales, 2018; Alig *et al.*, 2019). Complexes of iridium have held a central role in the development of pincer chemistry since the first known reports of organometallic pincer complexes (Moulton & Shaw, 1976), and are probably most notable for advances in homogeneous C—H activation chemistry and alkane dehydrogenation (Choi *et al.*, 2011). Pincer ligands have found widespread use due to their tunability, their ability to enforce reactive conformations,

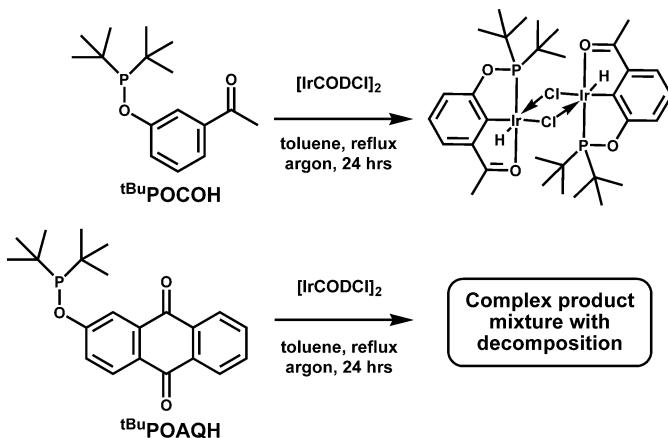

OPEN ACCESS

and the enhanced stability of these systems (van der Boom *et al.*, 2003; Roddick, 2013). The enhanced stability of pincer complexes largely stems from their tridentate binding mode; however, ligands intended as pincer-type do not always bind in a tridentate fashion. Sometimes bidentate, or even metal bridging, binding modes are encountered. Pincers bearing two phosphinite groups, known as POCOP ligands, have been particularly well studied (Morales-Morales, 2008). Previously, we reported a modification of this common framework bearing one phosphinite and one ketone group, 3-(di-*tert*-butylphosphinato)acetophenone, or  $^{t\text{Bu}}\text{POCOH}$  (Wilklow-Marnell & Brennessel, 2019). When refluxed in toluene for 24 h with 0.5 molar equivalents of  $[\text{Ir}(\text{COD})\text{Cl}]_2$  (COD = cycloocta-1,5-diene), the desired pincer-ligated iridium species was obtained in good yield (Fig. 1). However, when metalation of the related ligand, 2-(di-*tert*-butylphosphinato)anthraquinone ( $^{t\text{Bu}}\text{POAQH}$ ), was conducted under identical conditions, a mixture of unidentified products was obtained which resisted efforts to separate cleanly (Fig. 1).

Before any heating, and almost immediately upon mixing, a significant color change from orange to dark reddish brown was noted when  $^{t\text{Bu}}\text{POAQH}$  was reacted with  $[\text{Ir}(\text{COD})\text{Cl}]_2$  in toluene at room temperature, indicating that some degree of ligation of  $^{t\text{Bu}}\text{POAQH}$  had occurred. In light of the failure of forming a pincer complex when refluxed in toluene, the reaction was again attempted but allowed to remain at room

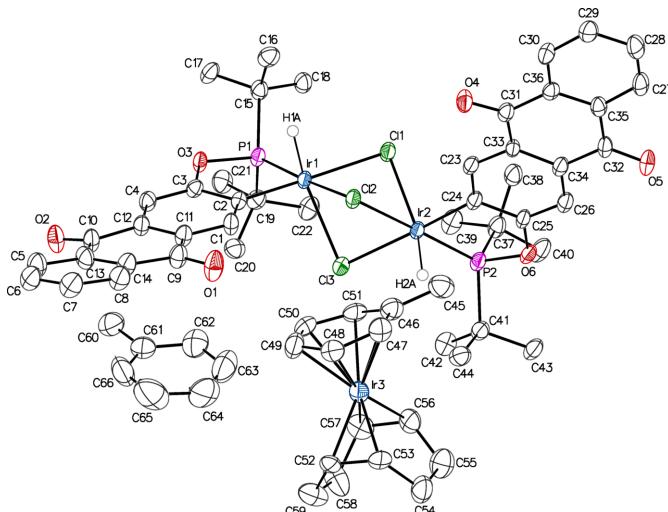

**Figure 1**

Successful metalation of  $^{t\text{Bu}}\text{POCOH}$  using  $[\text{Ir}(\text{COD})\text{Cl}]_2$  and attempted metalation of  $^{t\text{Bu}}\text{POAQH}$ .

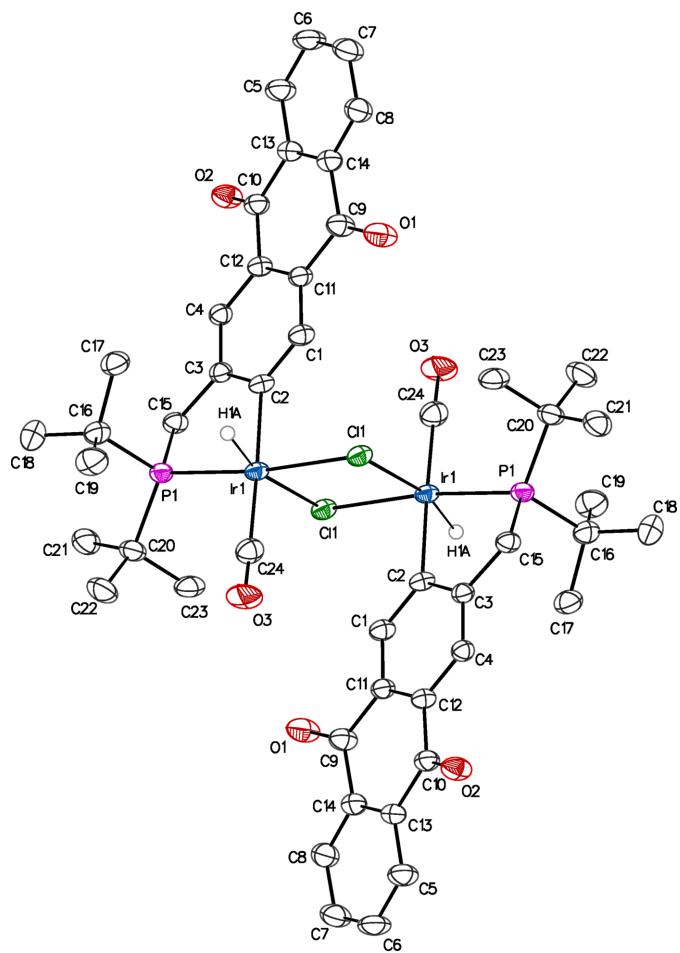

temperature. The  $^{31}\text{P}$  NMR spectrum indicated mainly a single product had formed with a resonance at 161 ppm in toluene and some free  $^{t\text{Bu}}\text{POAQH}$  remaining. Over a period of several days, a fine orange crystalline material separated from the solution, which was determined by single crystal structure determination to be the unique complex  $[\text{Ir}(\eta^6\text{-toluene})(\eta^2\text{-}\text{POAQH}_2)(\mu\text{-Cl})_3]\cdot\text{toluene}$  (**1**) as shown in Fig. 2. The formation and isolation of  $[\text{Ir}(\text{toluene})(\text{COD})]^+$  and other  $[\text{Ir}(\text{arene})(\text{COD})]^+$  complexes have been previously demonstrated (Sievert & Muetterties, 1981; Kanchiku *et al.*, 2007); however, a structure containing the  $[\text{Ir}(\text{toluene})(\text{COD})]^+$  cation has not yet been reported to date.

It was considered that under reflux conditions trace moisture may have led to hydrolysis of the ligand P—O bond, and the carbon analog, 2-(di-*tert*-butylphosphinomethyl) anthraquinone ( $^{t\text{Bu}}\text{PCAQH}$ ), was synthesized in hopes it might resist this. However, metalation of  $^{t\text{Bu}}\text{PCAQH}$  with  $[\text{Ir}(\text{COD})\text{Cl}]_2$  in refluxing toluene again failed to produce an

**Figure 2**

Anisotropic displacement ellipsoid plot of **1** drawn at the 50% probability level with all H atoms omitted except for hydrido ligands. The minor component of disorder is not shown.

**Figure 3**

isolable pincer-ligated product. When allowed to react and remain at room temperature, a solid material did eventually separate from solution; however, only polycrystalline material or crystals too small for diffraction were obtained.

When formed in toluene or chloroform, isolated and removed of volatiles under vacuum, then redissolved in chloroform (or deuteriochloroform) and exposed to an atmosphere of carbon monoxide, a change of color to pale yellow was noted. Crystals formed over a 16 h period. Single crystal X-ray diffraction revealed this product to be the charge neutral di-iridium complex,  $[\text{Ir}(\kappa\text{-}P,C\text{-PCAQ})\text{H}(\text{CO})(\mu\text{-Cl})]_2$  (**2**), with the intended pincer ligand again binding instead in a bidentate manner (Fig. 3). In this report, we provide the syntheses of both  $t^{\text{Bu}}\text{POAQH}$  and  $t^{\text{Bu}}\text{PCAQH}$  ligands, the isolation of complexes **1** and **2**, and compare their structures to related iridium complexes.

## 2. Structural commentary

Single-crystal X-ray diffraction analysis determined the structure of **1** to be a tri-iridium species with two iridium-

containing complex ions as a toluene solvate (Fig. 2). The asymmetric unit contains one monocationic iridium complex, one monoanionic di-iridium complex, and one toluene solvent molecule of crystallization, all in general positions in space group  $P\bar{1}$ . The anionic complex (**1an**) consists of two iridium(III) centers, each ligated by one bidentate  $t^{\text{Bu}}\text{POAQ}$  ligand *via* P and C atoms, one hydrido ligand (resulting from C–H activation of  $t^{\text{Bu}}\text{POAQH}$ ), and three bridging chlorido ligands. The geometry at each iridium center is distorted octahedral (Stiefel & Brown, 1972). The cationic complex (**1cat**) consists of an iridium(I) center bound  $\eta^6$  to a toluene ligand and bound in a bis- $\eta^2$  manner to unconjugated diene COD, giving a geometry akin to a ‘planar’ two-legged piano stool complex (Ward *et al.*, 1997), wherein the two legs are the midpoints of the double bonds of the COD ligand.

The majority, if not all, six-coordinate  $\text{Ir}^{\text{III}}$  complexes adopt octahedral geometries. In fact, as a molecular complex, there has yet to be a report of a trigonal-prismatic hexacoordinate iridium species to our knowledge (Yellowlees & Macnamara, 2003; Cremades *et al.*, 2010). The slight distortion from an octahedral arrangement seen in **1an** likely results from the steric bulk and restricted bite angle of the  $t^{\text{Bu}}\text{POAQ}$  ligand, as well as the limited separation of the three bridging chlorides which, as an  $\text{IrCl}_3$  unit, act as a tridentate ligand for the other iridium in the complex. Octahedral complexes are known to distort by undergoing trigonal twisting into a metaprismatic geometry somewhere between octahedral and trigonal prismatic forms when chelating ligands with rigid  $L\text{--}L$  distances are present (Cremades *et al.*, 2010; Alvarez, 2015). This occurs because most five-membered chelate rings display bite angles of  $< 90^\circ$  (Aguilà *et al.*, 2009), which better suit the ideal bond angle between ligands in a trigonal-prismatic geometry of  $81.8^\circ$ , as opposed to  $90^\circ$  for octahedral. However, the bite angle alone can only rarely induce a true trigonal-prismatic geometry.

In the case of the **1an**, the  $\text{Ir}\text{--Cl}$  bond lengths are not uniform, but the bonds *trans* to the hydrido ligands are much longer by comparison [2.5819 (11) Å *versus* 2.4782 (11) and 2.4818 (11) Å for Ir1; 2.5476 (11) *versus* 2.4963 (11) and 2.4780 (12) Å for Ir2; Table 1], fitting with the strong *trans*-influence of a hydrido ligand. The  $\text{Cl}\text{--Ir}\text{--Cl}$  bond angles have a range of 78.35 (4)–82.68 (4)°, and average to 80.38 (7)° at Ir1 and 80.64 (7)° at Ir2, quite close to the ideal angles of a trigonal-prismatic geometry [81.8°]. Ostensibly, the steric influence of *tert*-butyl groups from the  $t^{\text{Bu}}\text{POAQ}$  ligand on this are evident as the P–Ir–Cl bond angles for the two chlorides *cis* to P are rather large at 107.33 (4) and 101.24 (4)° for Ir1 and 106.79 (4) and 103.93 (4)° for Ir2, while the remaining bond angles at the metal centers do not deviate far from the ideal value of 90° for an octahedral complex. However, for related  $\text{Ir}-(\mu\text{-Cl})_3\text{--Ir}$  containing species with a range of ligand electronics/sterics, average  $\text{Cl}\text{--Ir}\text{--Cl}$  bond angles of roughly 79 to 82° are reported, indicating that the contraction of these angles is likely due mainly to the constraints of the  $\text{IrCl}_3$  fragment, as opposed to steric bulk of  $t^{\text{Bu}}\text{POAQ}$  or an electronic preference for a metaprismatic geometry (Allevi *et al.*, 1998; Zhang *et al.*, 2004; Maekawa *et al.*, 2004b; Dahlen-

burg *et al.*, 2008). The P—Ir—C angles of **1an** are appreciably constricted, averaging at  $82.16 (19)^\circ$ , due to being part of the five-membered chelate ring formed with  $^{t\text{Bu}}\text{POAQ}$ . Related  $^{t\text{Bu}}\text{POCOIr}$  and symmetric  $^R\text{POCOPIr}$  complexes for which structures have been determined display similar P—Ir—C bond angles, between approximately  $78.8$  to  $81.9^\circ$ , with larger angles associated with the less bulky mono-phosphinite POCO ligand, which can presumably approach closer to the metal. The Ir—P bond lengths of the reported structures (2.26 to 2.36  $\text{\AA}$ ) are comparable to those of **1an** (avg. 2.19 (16)  $\text{\AA}$ ; Wilklow-Marnell *et al.*, 2019; Göttker-Schnetmann *et al.*, 2004; Goldberg *et al.*, 2015; Shafiei-Haghghi *et al.*, 2018). With all anthraquinone C—O bond lengths of **1an** averaging 1.225 (13)  $\text{\AA}$ , and average C—C distances of 1.397 (17) and 1.392 (10)  $\text{\AA}$  for the proximal and distal aryl rings, respectively, bond lengths within the anthraquinone moiety of **1an** are in close agreement with those of free anthraquinone and representative 2,3-disubstituted anthraquinones 2,3-dichloroanthraquinone and 2-bromo-3-methylanthraquinone, indicating little electronic disturbance of the  $^{t\text{Bu}}\text{POAQ}$  aromatic system as would be expected for Ir<sup>III</sup> metal centers (Ketker *et al.*, 1981; Lenstra & van Loock, 1984; Il'in *et al.*, 1975; Pascal *et al.*, 2017).

Though long known in the literature (Muettterties *et al.*, 1979, 1981), the structure of the [Ir(toluene)(COD)]<sup>+</sup> cation (**1cat**) has yet to have been determined by diffraction studies, despite twenty other reported structures to date that contain

an  $[\text{Ir}(\eta^6\text{-arene})(\text{COD})]^+$  unit (see *Database survey*). The  $\eta^6$ -toluene ligand is not quite planar (r.m.s. deviation of 0.066  $\text{\AA}$ ). It is somewhat puckered toward iridium, with a fold along the C48···C51 vector: the angle between the C46—C48/C51 and C48—C51 planes is  $11.2 (6)^\circ$ . The Ir—C bond distances vary accordingly (Table 1).

The ring C=C bond lengths of the toluene ligand and those of the coordinated ethylene units of the COD ligand are indicative of significant backbonding from a low-valent Ir<sup>I</sup> center into the ligand  $\pi^*$  orbitals and are consistent with bond lengths seen in other structures with  $[\text{Ir}(\eta^6\text{-arene})(\text{COD})]^+$  or  $[\text{Rh}(\eta^6\text{-toluene})(\text{COD})]^+$  cations (see *Database survey*). The average ring C—C bond length of free toluene is 1.38  $\text{\AA}$  [Cambridge Structural Database (CSD), version 5.45, November 2023; Groom *et al.*, 2016], while that of the ligand in **1cat** is elongated at 1.413 (19)  $\text{\AA}$ . Likewise the average of the metal-coordinating C=C bonds of the COD ligand in **1cat** is 1.425 (13)  $\text{\AA}$ , as compared to that of free COD (1.333  $\text{\AA}$ ; Byrn *et al.*, 1990).

As determined by single-crystal X-ray diffraction, **2** was also found to contain a diiridium species (Fig. 3), but is neutral and is bridged by two chloride ligands as opposed to three as in **1**. If **2** goes through an intermediate similar to **1** following ligation of  $^{t\text{Bu}}\text{PCAQH}$  to iridium, then ostensibly, the third chloride has been displaced by coordination of one carbon monoxide (CO) ligand per iridium. Without the constraints of a third bridging chloride ligand, the geometry at iridium adopts a somewhat more idealized octahedral geometry, though still distorted by the steric demands of the  $^{t\text{Bu}}\text{PCAQ}$  ligand and remaining four-membered ring of the  $\text{Ir}_2(\mu\text{-Cl})_2$  unit (Table 2). As expected, the C2—Ir—P1 bond angle is contracted due to being part of a metallacycle to  $81.83 (10)^\circ$ , very similar to the average angle of  $82.3^\circ$  seen in the related structure of  $[\text{Ir}(\eta^2:\eta^2\text{-COD})_2 \cdot \{\eta^6\text{-}[\kappa^4\text{-C}_6\text{H}_2(\text{CH}_2\text{P}(t\text{Bu})_2]\text{Ir}_2\text{H}_2\text{Cl}_3\}]_2$  (Zhang *et al.*, 2004). In both structures, the fused-ring parts are not quite planar, with angles between the proximal and distal rings of  $12.0 (4)$  and  $7.9 (3)^\circ$  in **1**, and  $14.23 (15)^\circ$  in **2**.

### 3. Supramolecular features

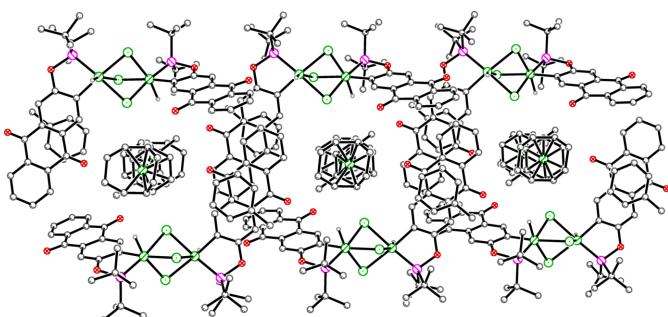

Molecules of **1an** are interlocked via offset parallel  $\pi\text{-}\pi$  interactions of inverted anthraquinone groups from adjacent

**Figure 5**

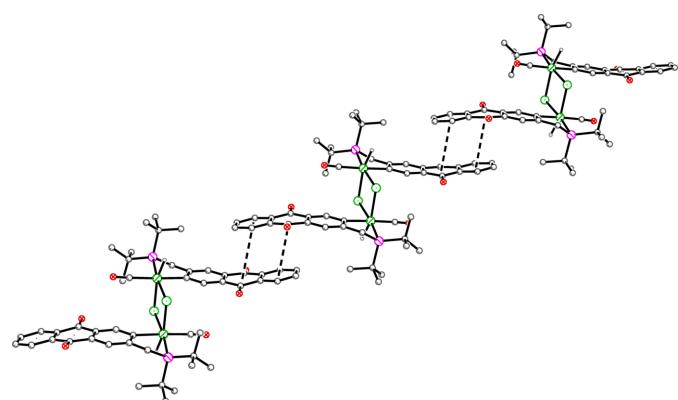

The recurring stacking of four  $\pi$  systems in **1**. The toluene–anthraquinone centroid–centroid distances are 3.85  $\text{\AA}$ . The anthraquinone–anthraquinone centroid–centroid distances are 3.82  $\text{\AA}$  (double dashed line) and 4.63  $\text{\AA}$  (single dashed line). Symmetry equivalent generated by  $-x, 1 - y, 1 - z$ .

with its corresponding shift of 2.805 (11)  $\text{\AA}$ , makes it unlikely for there to be any significant attractive force.] Inverted pairs of **1cat** fill the pockets created by the superstructure of the anions (Fig. 6), having an offset parallel orientation at a centroid–centroid distance of 4.165 (7)  $\text{\AA}$ , with a shift distance of 2.003 (13)  $\text{\AA}$  and angle between planes of 0 $^\circ$  (due to symmetry). These long distances may suggest that the arrangement is a consequence of efficient packing, rather than a true attractive force. Several weak non-traditional (C—H···O and C—H···Cl) hydrogen bonds are also present (Table 3).

In **2**, molecules are linked in one dimension along  $[10\bar{1}]$  by offset parallel  $\pi$ – $\pi$  interactions (Fig. 7), with centroid–centroid distances of 3.840 (2) and 3.966 (3)  $\text{\AA}$ , with respective shift

**Figure 6**

Offset parallel  $\pi$ – $\pi$  interactions of **1cat** with a centroid–centroid distance of 4.17  $\text{\AA}$ . Symmetry equivalent generated by  $1 - x, 1 - y, 1 - z$ .

**Figure 7**

Packing plot of **2**. The molecules are linked along  $[10\bar{1}]$  with centroid–centroid distances of 3.84  $\text{\AA}$  (double dashed line) and 3.97  $\text{\AA}$  (single dashed line).

**Table 4**Hydrogen-bond geometry ( $\text{\AA}$ ,  $^\circ$ ) for **2**.

Symmetry codes: (i)  $-x+1, -y+1, -z+1$ ; (ii)  $x+1, y, z$ ; (iii)  $-x+1, -y+1, -z+2$ .

distances of 1.404 (6) and 1.696 (7)  $\text{\AA}$  and angles between planes of 6.18 (15) and  $0^\circ$  (the latter exact due to symmetry). As in **1**, intermolecular non-traditional hydrogen bonds exist (Table 4).

#### 4. Database survey

To date there are ten structures containing two iridium centers bridged by three chlorido ligands: CSD refcodes GALQIT, GAMQIU (Allevi *et al.*, 1998); MOYLIV (Mura, 2000); DACCEQ, DACCIIU (Zhang *et al.*, 2004); MASNEA (Yellowlees *et al.*, 2005); UCEVEE (Viciano *et al.*, 2006); YIMVIA (Dahlenburg *et al.*, 2007); KIWTUG (Dahlenburg *et al.*, 2008); PIKVAK (Tatarin *et al.*, 2023).

Structures containing an  $[\text{Ir}(\eta^6\text{-arene})(\eta^2:\eta^2\text{-COD})]^+$  cationic unit are: CSD refcodes XIXTED (Ishii *et al.*, 2002); HUWRAS (Maekawa *et al.*, 2003); IMERAT, IMEREX, IRERIB, IMEROH, IMERUN (Muldoon & Brown, 2003); QUKLAJ, QUKLOX (Dorta *et al.*, 2004); ARACIF (Maekawa *et al.*, 2004a); DACCEQ (Zhang *et al.*, 2004); QOMXIA (Tejel *et al.*, 2008); XOWHOI (Melcher *et al.*, 2015); KAPZOT, KAPZUZ (Drover *et al.*, 2017); BUNXEQ (Bandera *et al.*, 2020); PUFGAB (Fisher *et al.*, 2020); VUQBUH (Linden & Dorta, 2020).

Structures containing the rhodium analog of **1cat**,  $[\text{Rh}(\eta^6\text{-toluene})(\eta^2:\eta^2\text{-COD})]^+$ , are: GERKUN (Sievers *et al.*, 2022); NIDHER, NIDJOD (Sumitani *et al.*, 2023).

#### 5. Synthesis and crystallization

All procedures were conducted under argon in a Vacuum Atmospheres Genesis glove box or *via* modified Schlenk techniques. All NMR spectra were collected on a JEOL JNM-ECZS 400 MHz spectrometer. All  $^{31}\text{P}$  NMR spectra were referenced to external  $\text{H}_3\text{PO}_4$ .  $^1\text{H}$  NMR spectra were referenced to residual deuterated solvent signal. All aromatic, alkane, or ether solvents were dried over sodium/benzophenone, distilled from the resultant purple solution prior to use, and stored over 3  $\text{\AA}$  molecular sieves.  $\text{CDCl}_3$  and  $\text{CHCl}_3$  were dried/stored with 3  $\text{\AA}$  molecular sieves activated by heating at 523 K under vacuum until a constant pressure of approx. 10 mTorr was reached. Methanol was dried by stirring with an excess of  $\text{CaH}_2$  until gas evolution through an outlet bubbler was observed to cease. It was stored over the  $\text{Ca}(\text{OH})_2$  and  $\text{Ca}(\text{OMe})_2$  formed, and distilled from this mixture as needed. Similarly, yellow triethylamine obtained commercially was reacted with  $\text{CaH}_2$  and vacuum transferred into a Schlenk ampoule for storage as a colorless liquid. All

other reagents were used as received from commercial sources without further purification.

#### 2-(Di-tert-butylphosphinito)anthraquinone ( ${}^{\text{tBu}}\text{POAQH}$ ):

To a 250 mL Erlenmeyer flask, 35 mg of NaH (1.46 mmol, 1.1 eq) and 75 mL of tetrahydrofuran (THF) were added followed by 0.40 mL (2.11 mmol, 1.6 eq) of di-*tert*-butylchlorophosphine and a stir bar. Then, while stirring, a solution of 300 mg (1.34 mmol) of 2-hydroxyanthraquinone in 100 mL of THF was added dropwise over a period of approximately 15 minutes providing a slightly cloudy purple mixture. Slow addition of quinone and relatively dilute reaction conditions were found to be important to minimize the formation of this unknown purple byproduct. After stirring for 72 h, the reaction mixture was filtered through a Celite pad on a fine glass frit and washed with THF (2  $\times$  5 mL). The maroon red filtrate was concentrated *in vacuo* until a brownish purple paste was obtained. The residue was stirred with toluene and refiltered to remove some reddish solids, then concentrated to dryness, and the process repeated twice more with hexane. Ultimately, a viscous green oil was obtained in 83% yield that provided NMR spectra consistent with the proposed product,  ${}^{\text{tBu}}\text{POAQH}$ , and of sufficient purity for further synthetic manipulations.  $^{31}\text{P}\{^1\text{H}\}$  NMR ( $\text{CDCl}_3$ ):  $\delta$  158.898 (s).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ):  $\delta$  8.33–8.22 (m, 3H), 8.00 (t,  $J$  = 2.2 Hz, 1H), 7.81–7.72 (m, virtual pentet of doublets, 2H), 7.6–7.53 (dt,  $J$  = 2.5, 8.8 Hz, 1H), 1.196 (s, 9H), 1.165 (s, 9H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ ):  $\delta$  183.25, 182.32, 165.15, 165.06, 135.61, 134.18, 133.76, 129.98, 127.47, 127.23, 123.91, 123.79, 116.21, 116.10, 36.16, 35.90, 27.43, 27.28.

#### 2-(Di-tert-butylphosphinomethyl)anthraquinone ( ${}^{\text{tBu}}\text{PCA-QH}$ ):

To a 50 mL round-bottom ampoule with a stir bar, 500 mg of 2-bromomethyl-anthraquinone (1.66 mmol) were added, followed by 291 mg of di-*tert*-butylphosphine (1.99 mmol, 1.2 eq). The vessel was then sealed, removed from the glove box, and connected to a Schlenk line. Approximately 30 mL of methanol were then added by vacuum transfer. The mixture was warmed to room temperature, and the sealed vessel then heated, with stirring, at 353 K for 72 h (note: a shorter reaction time may be possible, as all solid bromomethyl-anthraquinone dissolves within the first 12 h of reaction, indicative of solubilization through formation of the phosphonium bromide salt). After heating and cooling, 1.4 mL of triethylamine (10.0 mmol, 6 eq) were added by vacuum transfer. Upon thawing and stirring, copious formation of light solids (triethylammonium bromide) was observed, and the resultant mixture removed of volatiles *in vacuo*. In the glove box, the dry residue was extracted with THF and filtered through a fine frit until the  $\text{NH}_4\text{Br}$  solids were a free-flowing powder without stickiness. The clear yellow filtrate was concentrated to apparent dryness, but still retained excess phosphine. The solids were stirred in minimal toluene, filtered, washed with hexane, and dried *in vacuo* to provide 385 mg of a lustrous yellow solid. An additional 78 mg were obtained from the filtrate stored in a freezer overnight, making the total yield 75.8%.  $^{31}\text{P}\{^1\text{H}\}$  NMR ( $\text{CDCl}_3$ ):  $\delta$  39.61 (s).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ):  $\delta$  8.33–8.26 (m, 2H), 8.23–8.17 (m, 2H), 7.85–7.80 (dvt, 1H), 7.80–7.74 (m, 2H), 2.99 (d,  $J$  = 3.2, 2H), 1.17 (s, 9H), 1.14 (s, 9H).  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ ):  $\delta$  183.47, 183.11, 150.08, 149.96,

**[Ir(COD)(toluene)][(t<sup>Bu</sup>POAQIrH)<sub>2</sub>(μ-Cl)<sub>3</sub>] (1):** To a J-Young NMR tube, 15.5 mg of t<sup>Bu</sup>POAQH (42.07 μmol) were added followed by 14.1 mg of [Ir(COD)Cl]<sub>2</sub> (21.0 μmol dimer, 1 eq of Ir). 1 mL of toluene was then added, and the sealed tube was mixed. The solution rapidly adopted a dark red-brown color. <sup>31</sup>P-NMR spectroscopy in toluene revealed several products with chemical shifts at 181.5, 160.9, and 160.2 ppm. At 30 minutes after initial mixing, the singlet at 160.9 ppm was the major product, but this peak was observed to decrease with concomitant formation of small orange crystals from the solution. After 3–4 days the crystals were recovered by decanting the solvent and submitted for X-ray crystallographic analysis revealing the structure to be that of **1**.

**[Ir(κ-P,C-PCAQ)H(CO)Cl]<sub>2</sub> (2):** To a J-Young NMR tube, 12.0 mg of t<sup>Bu</sup>PCAQH (32.8 μmol) were added followed by 11.0 mg of [Ir(COD)Cl]<sub>2</sub> (16.4 μmol dimer, 1 eq of Ir). Then, 0.75 mL of CHCl<sub>3</sub> were added and the sealed tube mixed, providing an orange solution. <sup>31</sup>P-NMR spectroscopy showed a species with a chemical shift of 53.0 ppm as the major product, and spectra were effectively the same after 24 h. All volatiles were then removed by vacuum, using a warm water bath once CHCl<sub>3</sub> was evaporated to drive off residual excess COD. Following this, fresh CHCl<sub>3</sub> (or CDCl<sub>3</sub>) was added by vacuum transfer and the sample then exposed to 1 atm of carbon monoxide, which caused the solution to turn pale

yellow. Over a period of 1–2 days, **2** separated as yellow needles, which were isolated and submitted for X-ray diffraction studies.

## 6. Refinement

In **1**, the cation was modeled as disordered over two positions [0.894 (4):0.106 (4)]. Analogous bond lengths and angles between the two positions were restrained to be similar. Anisotropic displacement parameters for proximal atoms were restrained to be similar, and in the case of the minor component of disorder, restrained toward the expected motion relative to bond direction. The toluene solvent molecule of crystallization showed signs of minor disorder. The anisotropic displacement parameters along the bonding direction between two of the atoms (C63 and C64) were restrained to be similar.

The hydrido ligands' positions were based on peaks found in the difference-Fourier map. Once located, they were given riding models that preserved their angles relative to the other ligands, but with their Ir–H distances fixed at approximately 1.55 Å (based on an average obtained from the CSD for six-coordinate Ir complexes; Groom *et al.*, 2016). Their isotropic displacement parameters were refined relative to those of the Ir atoms:  $U_{\text{iso}}(\text{H}) = 2.0U_{\text{eq}}(\text{Ir})$ . Independent spectroscopic experiments confirm the presence of these ligands.

All other H atoms were placed geometrically and treated as riding atoms. Aromatic/*sp*<sup>2</sup>, C–H = 0.95 Å and methylene,

$C-H = 0.99 \text{ \AA}$ , with  $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$ . Methyl,  $C-H = 0.98 \text{ \AA}$ , with  $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$ .

In **2**, reflection contributions from highly disordered solvent were fixed and added to the calculated structure factors using the SQUEEZE routine of program *PLATON* (Spek, 2015), which determined there to be 184 electrons in  $492 \text{ \AA}^3$  treated this way per unit cell. Because the exact identity and amount of solvent were unknown, no solvent was included in the atom list or molecular formula. Thus all calculated quantities that derive from the molecular formula [e.g.,  $F(000)$ , density, molecular weight, etc.] are known to be inaccurate.

For **1** the maximum residual peak of  $1.52 \text{ e}^- \text{ \AA}^{-3}$  and the deepest hole of  $-1.72 \text{ e}^- \text{ \AA}^{-3}$  are found 1.15 and  $0.77 \text{ \AA}$  from atoms Ir1 and Ir2, respectively.

For **2** the maximum residual peak of  $0.99 \text{ e}^- \text{ \AA}^{-3}$  and the deepest hole of  $-1.03 \text{ e}^- \text{ \AA}^{-3}$  are found 0.95 and  $0.77 \text{ \AA}$  from atom Ir1.

Additional experimental and refinement details can be found in Table 5.

## Crystal structures of the ( $\eta^2$ : $\eta^2$ -cycloocta-1,5-diene)( $\eta^6$ -toluene)iridium(I) cation and $\mu$ -chlorido-iridium(III) complexes of 2-(phosphinito)- and 2-(phosphino-methyl)anthraquinone ligands

Sachin Thackeray, James Mahoney, Ashleigh Arrington, Miles Wilklow-Marnell and William W. Brennessel

### Computing details

( $\eta^2$ : $\eta^2$ -Cycloocta-1,5-diene)( $\eta^6$ -toluene)iridium(I) tri- $\mu$ -chlorido-bis({3-[di-*tert*-butylphosphanyl]oxy}-9,10-dioxoanthracen-2-yl}hydridoiridium(III)) toluene monosolvate, (1)

### Crystal data

[Ir(C <sub>7</sub> H <sub>8</sub> )(C <sub>8</sub> H <sub>12</sub> )·[Ir <sub>2</sub> H <sub>2</sub> (C <sub>22</sub> H <sub>24</sub> O <sub>3</sub> P) <sub>2</sub> Cl <sub>3</sub> ]·C <sub>7</sub> H <sub>8</sub>	Z = 2
M <sub>r</sub> = 1712.17	F(000) = 1668
Triclinic, P <bar>1</bar>	D <sub>x</sub> = 1.846 Mg m <sup>-3</sup>
a = 13.15698 (17) Å	Cu K $\alpha$ radiation, $\lambda$ = 1.54184 Å
b = 13.58360 (18) Å	Cell parameters from 23439 reflections
c = 17.5470 (3) Å	$\theta$ = 2.6–77.6°
$\alpha$ = 88.5722 (12)°	$\mu$ = 14.38 mm <sup>-1</sup>
$\beta$ = 87.0030 (12)°	T = 100 K
$\gamma$ = 79.7149 (11)°	Plate, orange
V = 3080.99 (8) Å <sup>3</sup>	0.10 × 0.05 × 0.01 mm

### Data collection

XtaLAB Synergy, Dualflex, HyPix	$T_{\min}$ = 0.643, $T_{\max}$ = 1.000
diffractometer	51464 measured reflections
Radiation source: micro-focus sealed X-ray	12864 independent reflections
tube, PhotonJet (Cu) X-ray Source	11114 reflections with $I > 2\sigma(I)$
Mirror monochromator	$R_{\text{int}}$ = 0.056
Detector resolution: 10.0000 pixels mm <sup>-1</sup>	$\theta_{\max}$ = 78.2°, $\theta_{\min}$ = 2.5°
$\omega$ scans	$h$ = -16→14
Absorption correction: multi-scan	$k$ = -16→17
(CrysAlisPro; Rigaku OD, 2023)	$l$ = -22→21

### Refinement

Refinement on $F^2$	Secondary atom site location: difference Fourier map
Least-squares matrix: full	Hydrogen site location: mixed
$R[F^2 > 2\sigma(F^2)]$ = 0.035	H-atom parameters constrained
wR( $F^2$ ) = 0.092	$w = 1/[\sigma^2(F_o^2) + (0.0514P)^2 + 3.1792P]$
$S$ = 1.04	where $P = (F_o^2 + 2F_c^2)/3$
12864 reflections	$(\Delta/\sigma)_{\max}$ = 0.002
881 parameters	$\Delta\rho_{\max}$ = 1.52 e Å <sup>-3</sup>
395 restraints	$\Delta\rho_{\min}$ = -1.72 e Å <sup>-3</sup>
Primary atom site location: dual	

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** The  $[\text{Ir}(\text{toluene})(\text{COD})]^+$  cation is modeled as disordered over two positions (0.894 (4):0.106 (4)).

Analogous bond lengths and angles between the two positions of the disordered cation were restrained to be similar. Anisotropic displacement parameters for proximal atoms were restrained to be similar, and in the case of the minor component of disorder, restrained toward the expected motion relative to bond direction.

The hydrido ligands' positions were based on peaks found in the difference Fourier map. Once located, they were given riding models that preserved their angles relative to the other ligands, but with their Ir–H distances fixed at approximately 1.55 Å (based on an average obtained from the Cambridge Structural Database for six-coordinate Ir complexes; Groom *et al.*, 2016). Independent spectroscopic experiments confirm the presence of these ligands.

The toluene solvent molecule of crystallization showed signs of minor disorder. The anisotropic displacement parameters along the bonding direction between two of the atoms (C63 and C64) were restrained to be similar.

$\Delta\rho_{\min} = -1.03 \text{ e \AA}^{-3}$

*Special details*

**Geometry.** All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

**Refinement.** Reflection contributions from highly disordered solvent were fixed and added to the calculated structure factors using the SQUEEZE routine of program Platon (Spek, 2015), which determined there to be 184 electrons in 492  $\text{\AA}^3$  treated this way per unit cell. Because the exact identity and amount of solvent were unknown, no solvent was included in the atom list or molecular formula. Thus all calculated quantities that derive from the molecular formula (e.g.,  $F(000)$ , density, molecular weight, etc.) are known to be inaccurate.

The hydrido ligand's position was based on a peak found in the difference Fourier map. Once located, it was given a riding model that preserved its angle relative to the other ligands, but with its Ir-H distance fixed at approximately 1.55  $\text{\AA}$  (based on an average obtained from the Cambridge Structural Database for six-coordinate Ir complexes; Groom *et al.*, 2016). Independent spectroscopic experiments confirm the presence of this ligand.
